CS425: Algorithms for Web Scale Data

## Lecture 3: Similarity Modeling

[Hays and Efros, SIGGRAPH 2007]

## Scene Completion Problem

[Hays and Efros, SIGGRAPH 2007]

## Scene Completion Problem

## Scene Completion Problem

[Hays and Efros, SIGGRAPH 2007]

## Scene Completion Problem

10 nearest neighbors from a collection of 2 million images

## A Common Metaphor

- Many problems can be expressed as finding "similar" sets:
- Find near-neighbors in high-dimensional space
- Examples:
- Pages with similar words
- For duplicate detection, classification by topic
- Customers who purchased similar products
- Products with similar customer sets
- Images with similar features

## Problem for Today's Lecture

- Given: High dimensional data points $x_{1}, x_{2}, \ldots$
- For example: Image is a long vector of pixel colors

$$
\left[\begin{array}{lll}
1 & 2 & 1 \\
0 & 2 & 1 \\
0 & 1 & 0
\end{array}\right] \rightarrow\left[\begin{array}{lllllllll}
1 & 2 & 1 & 0 & 2 & 1 & 0 & 1 & 0
\end{array}\right]
$$

- And some distance function $d\left(x_{1}, x_{2}\right)$
" Which quantifies the "distance" between $x_{1}$ and $x_{2}$
- Goal: Find all pairs of data points $\left(x_{i}, x_{j}\right)$ that are within some distance threshold $\boldsymbol{d}\left(\boldsymbol{x}_{\boldsymbol{i}}, \boldsymbol{x}_{\boldsymbol{j}}\right) \leq \boldsymbol{s}$
- Note: Naïve solution would take $\boldsymbol{O}\left(N^{2}\right)$ : where $\boldsymbol{N}$ is the number of data points
- MAGIC: This can be done in $\boldsymbol{O}(N)$ !! How?

## Finding Similar Items

## Distance Measures

- Goal: Find near-neighbors in high-dim. space
- We formally define "near neighbors" as points that are a "small distance" apart
- For each application, we first need to define what "distance" means
- Today: Jaccard distance/similarity
- The Jaccard similarity of two sets is the size of their intersection divided by the size of their union: $\operatorname{sim}\left(\mathrm{C}_{1}, \mathrm{C}_{2}\right)=\left|\mathrm{C}_{1} \cap \mathrm{C}_{2}\right| /\left|\mathrm{C}_{1} \cup \mathrm{C}_{2}\right|$
- Jaccard distance: $d\left(C_{1}, C_{2}\right)=1-\left|C_{1} \cap C_{2}\right| /\left|C_{1} \cup C_{2}\right|$

3 in intersection 8 in union Jaccard similarity $=3 / 8$ Jaccard distance $=5 / 8$

## Task: Finding Similar Documents

- Goal: Given a large number ( $N$ in the millions or billions) of documents, find "near duplicate" pairs
- Applications:
- Mirror websites, or approximate mirrors
- Don't want to show both in search results
- Similar news articles at many news sites
- Cluster articles by "same story"
- Problems:
- Many small pieces of one document can appear out of order in another
- Too many documents to compare all pairs
- Documents are so large or so many that they cannot fit in main memory

## 3 Essential Steps for Similar Docs

1. Shingling: Convert documents to sets
2. Min-Hashing: Convert large sets to short signatures, while preserving similarity
3. Locality-Sensitive Hashing: Focus on pairs of signatures likely to be from similar documents

- Candidate pairs!

## The Big Picture

## Step 1: Shingling: Convert documents to sets

## Define: Shingles

- A $k$-shingle (or $k$-gram) for a document is a sequence of $k$ tokens that appears in the doc
- Tokens can be characters, words or something else, depending on the application
- Assume tokens = characters for examples
- Example: $\mathbf{k}=\mathbf{2}$; document $\mathbf{D}_{1}=a b c a b$ Set of 2-shingles: $\mathbf{S}\left(\mathrm{D}_{1}\right)=\{a b, b c, c a\}$
- Option: Shingles as a bag (multiset), count ab twice: $\mathbf{S}^{\prime}\left(\mathbf{D}_{1}\right)=\{a b, b c, c a, a b\}$

## Examples

$\square$ Input text:
"The most effective way to represent documents as sets is to construct from the document the set of short strings that appear within it."
$\square$ 5-shingles:
"The m", "he mo", "e mos", " most", " ost ", "ost e", "st ef", "t eff", " effe", "effec", "ffect", "fecti", "ectiv", ...
$\square$ 9-shingles:
"The most ", "he most e", "e most ef", " most eff", "most effe",
"ost effec", "st effect", "t effecti"," effectiv", "effective", ...

## Hashing Shingles

$\square$ Storage of k-shingles: $k$ bytes per shingle
$\square$ Instead, hash each shingle to a 4-byte integer.

- E.g. "The most" $\rightarrow 4320$
"he moste" $\rightarrow 56456$
"e most ef" $\rightarrow 214509$
$\square$ Which one is better?

1. Using 4 shingles?
2. Using 9 -shingles, and then hashing each to 4 byte integer?
$\square$ Consider the \# of distinct elements represented with 4 bytes

## Hashing Shingles

$\square$ Not all characters are common.

- e.g. Unlikely to have shingles like "zy\%p"
$\square$ Rule of thumb: \# of $k$-shingles is about $20^{k}$
$\square$ Using 4-shingles:
ㅁ \# of shingles: $20^{4}=160 \mathrm{~K}$
$\square$ Using 9-shingles and then hashing to 4-byte values:
- \# of shingles: $20^{9}=512 \mathrm{~B}$

ㅁ \# of buckets: $2^{32}=4.3 B$

- 512B shingles (uniformly) distributed to 4.3B buckets

## Similarity Metric for Shingles

- Document $D_{1}$ is a set of its k-shingles $C_{1}=S\left(D_{1}\right)$
- Equivalently, each document is a $0 / 1$ vector in the space of $k$-shingles
- Each unique shingle is a dimension
- Vectors are very sparse
- A natural similarity measure is the Jaccard similarity:

$$
\operatorname{sim}\left(D_{1}, D_{2}\right)=\left|C_{1} \cap C_{2}\right| /\left|C_{1} \cup C_{2}\right|
$$

## Working Assumption

- Documents that have lots of shingles in common have similar text, even if the text appears in different order
- Caveat: You must pick $\boldsymbol{k}$ large enough, or most documents will have most shingles
- $\boldsymbol{k}=5$ is OK for short documents
- $\boldsymbol{k}=10$ is better for long documents

## Motivation for Minhash/LSH

- Suppose we need to find near-duplicate documents among $N=1$ million documents
- Naïvely, we would have to compute pairwise Jaccard similarities for every pair of docs
- $N(N-1) / 2 \approx 5^{*} 0^{11}$ comparisons
- At $10^{5}$ secs/day and $10^{6}$ comparisons/sec, it would take 5 days
- For $\boldsymbol{N}=\mathbf{1 0}$ million, it takes more than a year...

## Step 2: Minhashing: Convert large sets to short signatures, while preserving similarity

## Encoding Sets as Bit Vectors

- Many similarity problems can be formalized as finding subsets that
 have significant intersection
- Encode sets using 0/1 (bit, boolean) vectors
- One dimension per element in the universal set
- Interpret set intersection as bitwise AND, and set union as bitwise OR
- Example: $\mathrm{C}_{1}=10111 ; \mathrm{C}_{\mathbf{2}}=10011$
- Size of intersection $=3$; size of union $=4$,
- Jaccard similarity (not distance) = 3/4
- Distance: $d\left(C_{1}, C_{2}\right)=1$ - (Jaccard similarity) $=1 / 4$

## From Sets to Boolean Matrices

- Rows = elements (shingles)
- Columns = sets (documents)
- 1 in row $\boldsymbol{e}$ and column $\boldsymbol{s}$ if and only if $\boldsymbol{e}$ is a member of $\boldsymbol{s}$
- Column similarity is the Jaccard similarity of the corresponding sets (rows with value 1)
- Typical matrix is sparse!
- Each document is a column:
- Example: $\operatorname{sim}\left(\mathrm{C}_{1}, \mathrm{C}_{2}\right)=$ ?
- Size of intersection $=3$; size of union $=6$, Jaccard similarity (not distance) $=3 / 6$
- $d\left(C_{1}, C_{2}\right)=1$ - (Jaccard similarity) = 3/6

Documents

| 1 | 1 | 1 | 0 |
| :--- | :--- | :--- | :--- |
| 1 | 1 | 0 | 1 |
| 0 | 1 | 0 | 1 |
| $\frac{0}{0}=0$ | 0 | 0 | 1 |
| 1 | 0 | 0 | 1 |
| 1 | 1 | 1 | 0 |
| 1 | 0 | 1 | 0 |

## Outline: Finding Similar Columns

- So far:
- Documents $\rightarrow$ Sets of shingles
- Represent sets as boolean vectors in a matrix
- Next goal: Find similar columns while computing small signatures
- Similarity of columns $==$ similarity of signatures

## Hashing Columns (Signatures)

- Key idea: "hash" each column C to a small signature $h(C)$, such that:
- (1) $h(C)$ is small enough that the signature fits in RAM
- (2) $\operatorname{sim}\left(C_{1}, C_{2}\right)$ is the same as the "similarity" of signatures $\boldsymbol{h}\left(\boldsymbol{C}_{1}\right)$ and $\boldsymbol{h}\left(\boldsymbol{C}_{2}\right)$
- Goal: Find a hash function $h(\cdot)$ such that:
- If $\operatorname{sim}\left(\boldsymbol{C}_{1}, \boldsymbol{C}_{2}\right)$ is high, then with high prob. $\boldsymbol{h}\left(\boldsymbol{C}_{1}\right)=\boldsymbol{h}\left(\boldsymbol{C}_{2}\right)$
- If $\operatorname{sim}\left(C_{1}, C_{2}\right)$ is low, then with high prob. $\boldsymbol{h}\left(\boldsymbol{C}_{1}\right) \neq \boldsymbol{h}\left(\boldsymbol{C}_{2}\right)$
- Hash docs into buckets. Expect that "most" pairs of near duplicate docs hash into the same bucket!

## Min-Hashing

- Goal: Find a hash function $h(\cdot)$ such that:
" if $\operatorname{sim}\left(C_{1}, C_{2}\right)$ is high, then with high prob. $h\left(C_{1}\right)=h\left(C_{2}\right)$
- if $\operatorname{sim}\left(C_{1}, C_{2}\right)$ is low, then with high prob. $h\left(C_{1}\right) \neq h\left(C_{2}\right)$
- Clearly, the hash function depends on the similarity metric:
- Not all similarity metrics have a suitable hash function
- There is a suitable hash function for the Jaccard similarity: It is called Min-Hashing

## Min-Hashing

- Imagine the rows of the boolean matrix permuted under random permutation $\boldsymbol{\pi}$
- Define a "hash" function $h_{\pi}(C)=$ the index of the first (in the permuted order $\pi$ ) row in which column $C$ has value $\mathbf{1}$ :

$$
h_{\pi}(C)=\min _{\pi} \pi(C)
$$

- Use several (e.g., 100) independent hash functions (that is, permutations) to create a signature of a column

Min-Hashing Example

## Min-Hashing Example

$2^{\text {nd }}$ element of the permutation

| Permutation Input matrix (Shingles $\times$ Documents) $\quad$ Signature matrix $M$ |  |  |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 2 | 4 | 3 | $1 \downarrow$ | 0 | 1 | 0 | 2 | 1 | 2 | 1 |
| 3 | 2 | 4 | 1 | 0 | 0 |  | 2 | 1 | 4 | 1 |
| 7 | 1 | 7 | 0 |  | 0 |  | $1$ |  | 1 | 2 |
| 6 | 3 | 2 | 0 | 1 | 0 |  |  |  |  |  |
| 1 | 6 | 6 | 0 | 1 | 0 | 1 |  |  |  | tiol |
| 5 | 7 | 1 | 1 | 0 | 1 | 0 |  |  |  |  |
| 4 | 5 | 5 | 1 | 0 | 1 | 0 |  |  |  |  |

## The Min-Hash Property

- Choose a random permutation $\pi$
$\square \underline{\left.\text { Claim: } \operatorname{Pr}\left[h_{\pi}\left(\mathrm{C}_{\mathrm{i}}\right)=h_{\pi}\left(\mathrm{C}_{\mathrm{j}}\right)\right]=\operatorname{sim}\left(\mathrm{C}_{\mathrm{i}}, \mathrm{C}_{\mathrm{j}}\right), ~()^{2}\right)}$
$\square$ Proof:
- Consider 3 types of rows:
type X : $\mathrm{C}_{\mathrm{i}}$ and $\mathrm{C}_{\mathrm{j}}$ both have 1 s
type Y : only one of $\mathrm{C}_{\mathrm{i}}$ and $\mathrm{C}_{\mathrm{j}}$ has 1
type Z : $\mathrm{C}_{\mathrm{i}}$ and $\mathrm{C}_{\mathrm{j}}$ both have 0 s
- After random permutation $\pi$, what if the first X-type row is before the first Y-type row?

$$
h_{\pi}\left(\mathrm{C}_{\mathrm{i}}\right)=h_{\pi}\left(\mathrm{C}_{\mathrm{j}}\right)
$$

Input Matrix

## The Min-Hash Property

$\square$ What is the probability that the first not-Z row is of type X ?

$$
\frac{|X|}{|X|+|Y|}
$$

$\square \operatorname{Pr}\left[h_{\pi}\left(\mathbf{C}_{\mathbf{i}}\right)=\boldsymbol{h}_{\boldsymbol{\pi}}\left(\mathrm{C}_{\mathrm{j}}\right)\right]=\frac{|X|}{|X|+|Y|}$
$\square \operatorname{sim}\left(\mathrm{C}_{\mathrm{i}}, \mathrm{C}_{\mathrm{j}}\right)=\frac{\left|C_{i} \cap C_{\mathrm{i}}\right|}{\left|C_{i} \cup C_{\mathrm{j}}\right|}=\frac{|X|}{|X|+|Y|}=\operatorname{Pr}\left[h_{\pi}\left(\mathrm{C}_{\mathrm{i}}\right)=h_{\pi}\left(\mathrm{C}_{\mathrm{j}}\right)\right]$
$\square$ Conclusion: $\operatorname{Pr}\left[h_{\pi}\left(\mathbf{C}_{\mathbf{i}}\right)=\boldsymbol{h}_{\pi}\left(\mathrm{C}_{\mathrm{j}}\right)\right]=\operatorname{sim}\left(\mathrm{C}_{\mathbf{i}}, \mathrm{C}_{\mathbf{j}}\right)$

## Similarity for Signatures

- We know: $\operatorname{Pr}\left[h_{\pi}\left(\mathrm{C}_{1}\right)=h_{\pi}\left(\mathrm{C}_{2}\right)\right]=\operatorname{sim}\left(\mathrm{C}_{1}, \mathrm{C}_{2}\right)$
- Now generalize to multiple hash functions
- The similarity of two signatures is the fraction of the hash functions in which they agree
- Note: Because of the Min-Hash property, the similarity of columns is the same as the expected similarity of their signatures

## Min-Hashing Example

Permutation $\pi \quad$ Input matrix (Shingles $x$ Documents)

| 2 | 4 | 3 |
| :--- | :--- | :--- | :--- |
| 3 | 2 | 4 |
| 7 | 1 | 7 |
| 6 | 3 | 2 |
| 1 | 6 | 6 |
| 5 | 7 | 1 |
| 4 | 5 | 5 |

| 1 | 0 | 1 | 0 |
| :--- | :--- | :--- | :--- |
| 1 | 0 | 0 | 1 |
| 0 | 1 | 0 | 1 |
| 0 | 1 | 0 | 1 |
| 0 | 1 | 0 | 1 |
| 1 | 0 | 1 | 0 |
| 1 | 0 | 1 | 0 |

Signature matrix $M$

Similarities:

|  | $1-3$ | $2-4$ | $1-2$ | $3-4$ |
| :--- | :--- | :--- | :--- | :--- |
| Col/Col | 0.75 | 0.75 | 0 | 0 |
| Sig/Sig | 0.67 | 1.00 | 0 | 0 |
|  |  |  |  |  |

## Similarity of Signatures

$\square$ What is the expected value of Jaccard similarity of two signatures $\operatorname{sig}_{1}$ and $\operatorname{sig}_{2}$ ? Assume there are $\mathbf{s}$ min-hash values in each signature.

$$
\begin{aligned}
E\left[\operatorname{sim}\left(\operatorname{sig}_{1}, \operatorname{sig}_{2}\right)\right] & =E\left[\frac{\# \text { of } \pi \text { s.t. } h_{\pi}\left(C_{1}\right)=h_{\pi}\left(C_{2}\right)}{s}\right] \\
& =\frac{1}{s} \sum_{=1}^{s} \operatorname{Pr}\left[h_{\pi}\left(\mathrm{C}_{1}\right)=\mathrm{h}_{\pi}\left(C_{2}\right)\right] \\
& =\operatorname{sim}\left(C_{1}, C_{2}\right)
\end{aligned}
$$

$\square$ Law of large numbers: Average of the results obtained from a large number of trials should be close to the expected value, and will tend to become closer as more trials are performed.

## Min-Hash Signatures

- Pick K=100 random permutations of the rows
- Think of $\boldsymbol{\operatorname { s i g }}(\mathrm{C})$ as a column vector
- $\boldsymbol{\operatorname { s i g }}(\mathrm{C})[i]=$ according to the $i$-th permutation, the index of the first row that has a 1 in column $C$

$$
\operatorname{sig}(\mathrm{C})[\mathrm{i}]=\min \left(\pi_{\mathrm{i}}(\mathrm{C})\right)
$$

- Note: The sketch (signature) of document $C$ is small $\sim 400$ bytes!
- We achieved our goal! We "compressed" long bit vectors into short signatures

## Implementation Trick

- Permuting rows even once is prohibitive
- Row hashing!
- Pick K=100 hash functions $\boldsymbol{k}_{\boldsymbol{i}}$
- Ordering under $\boldsymbol{k}_{\boldsymbol{i}}$ gives a random row (almost) permutation!

Hash func. 1 Hash func. 2

| Row | $\mathbf{D}_{1}$ | $\mathbf{D}_{2}$ | $\mathbf{D}_{3}$ | $\mathbf{D}_{4}$ | $(r+1) \% 5$ | $(3 r+1) \% 5$ |
| ---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 0 | 1 | 0 | 0 | 1 | 1 | 1 |
| 1 | 0 | 0 | 1 | 0 | 2 | 4 |
| 2 | 0 | 1 | 0 | 1 | 3 | 2 |
| 3 | 1 | 0 | 1 | 1 | 4 | 0 |
| 4 | 0 | 0 | 1 | 0 | 0 | 3 |

How to pick a random hash function $h(x)$ ?
Universal hashing:
$h_{a, b}(x)=((a \cdot x+b) \bmod p) \bmod N$ where:
a,b ... random integers
p ... prime number ( $\mathrm{p}>\mathrm{N}$ )

## Implementation Trick

One-pass implementation

- For each column $\boldsymbol{C}$ and hash-func. $\boldsymbol{k}_{\boldsymbol{i}}$ keep a "slot" for the min-hash value
- Initialize all sig(C)[i] = $\infty$
- Scan rows looking for 1s
- Suppose row $\boldsymbol{j}$ has 1 in column $\boldsymbol{C}$
- Then for each $\boldsymbol{k}_{\boldsymbol{i}}$ :
- If $\boldsymbol{k}_{i}(j)<\operatorname{sig}(C)[i]$, then $\operatorname{sig}(C)[i] \leftarrow \boldsymbol{k}_{i}(j)$

## Example: Computing Min-Hash Signatures

| 4 | 0 | 0 | 1 | 0 | 0 | 3 |

Signatures

| $D_{1}$ | $D_{2}$ | $D_{3}$ | $D_{4}$ |
| :---: | :---: | :---: | :---: |
| 1 | 3 | 0 | 1 |
| 0 | 2 | 0 | 0 |

## Example: Computing Min-Hash Signatures

Hash func. 1 Hash func. 2

| Row | $\mathbf{D}_{1}$ | $\mathbf{D}_{2}$ | $\mathbf{D}_{3}$ | $\mathbf{D}_{4}$ | $(\mathrm{r}+1) \% 5$ | $(3 \mathrm{r}+1) \% 5$ |
| ---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 0 | 1 | 0 | 0 | 1 | 1 | 1 |
| 1 | 0 | 0 | 1 | 0 | 2 | 4 |
| 2 | 0 | 1 | 0 | 1 | 3 | 2 |
| 3 | 1 | 0 | 1 | 1 | 4 | 0 |
| 4 | 0 | 0 | 1 | 0 | 0 | 3 |

Final signatures

| $D_{1}$ | $D_{2}$ | $D_{3}$ | $D_{4}$ |
| :---: | :---: | :---: | :---: |
| 1 | 3 | 0 | 1 |
| 0 | 2 | 0 | 0 |

Step 3: Locality-Sensitive Hashing:
Focus on pairs of signatures likely to be from similar documents

LSH: First Cut

| 2 | 1 | 4 | 1 |
| :--- | :--- | :--- | :--- |
| 1 | 2 | 1 | 2 |
| 2 | 1 | 2 | 1 |

- Goal: Find documents with Jaccard similarity at least $s$ (for some similarity threshold, e.g., $s=0.8$ )
- LSH - General idea: Use a function $f(x, y)$ that tells whether $\boldsymbol{x}$ and $\boldsymbol{y}$ is a candidate pair: a pair of elements whose similarity must be evaluated
- For Min-Hash matrices:
- Hash columns of signature matrix $M$ to many buckets
- Each pair of documents that hashes into the same bucket is a candidate pair

# LSH for Min-Hash <br> $$
1
$$ <br> <div class="inline-tabular"><table id="tabular" data-type="subtable">
<tbody>
<tr style="border-top: none !important; border-bottom: none !important;">

- Big idea: Hash columns of signature matrix $M$ several times
- Arrange that (only) similar columns are likely to hash to the same bucket, with high probability
- Candidate pairs are those that hash to the same bucket

## Partition M into b Bands

| 2 | 1 | 4 | 1 |
| :--- | :--- | :--- | :--- |
| 1 | 2 | 1 | 2 |
| 2 | 1 | 2 | 1 |

Signature matrix $M$

## Partition M into Bands

- Divide matrix $\boldsymbol{M}$ into $\boldsymbol{b}$ bands of $\boldsymbol{r}$ rows
- For each band, hash its portion of each column to a hash table with $\boldsymbol{k}$ buckets
- Make $\boldsymbol{k}$ as large as possible
- Candidate column pairs are those that hash to the same bucket for $\geq \mathbf{1}$ band
- Tune $\boldsymbol{b}$ and $\boldsymbol{r}$ to catch most similar pairs, but few non-similar pairs

## Hashing Bands

False negative?

Buckets

Candidate pairs: $\{(2,4) ;(1,6) ;(3,8)\}$

## Simplifying Assumption

- There are enough buckets that columns are unlikely to hash to the same bucket unless they are identical in a particular band
- Hereafter, we assume that "same bucket" means "identical in that band"
- Assumption needed only to simplify analysis, not for correctness of algorithm

## Example of Bands

| 2 | 1 | 4 | 1 |
| :--- | :--- | :--- | :--- |
| 1 | 2 | 1 | 2 |
| 2 | 1 | 2 | 1 |

Assume the following case:

- Suppose 100,000 columns of $\boldsymbol{M}$ (100k docs)
- Signatures of 100 integers (rows)
- Therefore, signatures take 40Mb
- Choose $\boldsymbol{b}=20$ bands of $\boldsymbol{r}=5$ integers/band
- Goal: Find pairs of documents that are at least $\boldsymbol{s}=0.8$ similar
- Find pairs of $\geq s=0.8$ similarity, set $b=20, r=5$
- Assume: $\operatorname{sim}\left(C_{1}, C_{2}\right)=0.8$
- Since $\operatorname{sim}\left(C_{1}, C_{2}\right) \geq \mathbf{s}$, we want $C_{1}, C_{2}$ to be a candidate pair: We want them to hash to at least 1 common bucket (at least one band is identical)
- Probability $\mathrm{C}_{1}, \mathrm{C}_{2}$ identical in one particular band:

$$
(0.8)^{5}=0.328
$$

- Probability $\mathrm{C}_{1}, \mathrm{C}_{2}$ are different in all of the 20 bands:

$$
(1-0.328)^{20}=0.00035
$$

- i.e., about $1 / 3000$ th of the $80 \%$-similar column pairs are false negatives (we miss them)
- We would find 99.965\% pairs of truly similar documents
$2 \quad 1 \quad 4$
- Find pairs of $\geq s=0.8$ similarity, set $b=20, r=5$
- Assume: $\operatorname{sim}\left(C_{1}, C_{2}\right)=0.3$
- Since $\operatorname{sim}\left(C_{1}, C_{2}\right)<s$ we want $C_{1}, C_{2}$ to hash to NO common buckets (all bands should be different)
- Probability $\mathrm{C}_{1}, \mathrm{C}_{2}$ identical in one particular band:

$$
(0.3)^{5}=0.00243
$$

- Probability $\mathrm{C}_{1}, \mathrm{C}_{2}$ identical in at least 1 of 20 bands:

$$
1-(1-0.00243)^{20}=0.0474
$$

- In other words, approximately $4.74 \%$ pairs of docs with similarity $0.3 \%$ end up becoming candidate pairs
- They are false positives since we will have to examine them (they are candidate pairs) but then it will turn out their similarity is below threshold s

# LSH Involves a Tradeoff <br>  <br> $\begin{array}{llll}2 & 1 & 2 & 1\end{array}$ 

- Pick:
- The number of Min-Hashes (rows of $\boldsymbol{M}$ )
- The number of bands $\boldsymbol{b}$, and
- The number of rows $r$ per band
to balance false positives/negatives
- Example: How would the false positives/negatives change if we had only 15 bands of 5 rows (as opposed to 20 bands of 5 rows)?
- The number of false positives would go down, but the number of false negatives would go up

## Analysis of LSH - What We Want

Similarity $t=\operatorname{sim}\left(C_{1}, C_{2}\right)$ of two sets

## What 1 Band of 1 Row Gives You

Similarity $t=\operatorname{sim}\left(C_{1}, C_{2}\right)$ of two sets

## $b$ bands, $r$ rows/band

- Columns $\mathrm{C}_{1}$ and $\mathrm{C}_{2}$ have similarity $t$
- Pick any band (r rows)
- Prob. that all rows in band equal

$$
\boldsymbol{t}^{r}
$$

- Prob. that some row in band unequal

$$
1-t^{r}
$$

- Prob. that no band identical

$$
\left(1-t^{r}\right)^{b}
$$

- Prob. that at least 1 band identical

$$
1-\left(1-t^{r}\right)^{b}
$$

## What $b$ Bands of $r$ Rows Gives You

## Example: $b=20 ; r=5$

- Similarity threshold s
- Prob. that at least 1 band is identical:

| $\boldsymbol{s}$ | $\mathbf{1 - ( 1 - \mathbf { s } ^ { \mathbf { r } } ) ^ { \mathbf { b } }}$ |
| :---: | :---: |
| .2 | .006 |
| .3 | .047 |
| .4 | .186 |
| .5 | .470 |
| .6 | .802 |
| .7 | .975 |
| .8 | .9996 |

## Picking $r$ and $b$ : The S-curve

- Picking $r$ and $b$ to get the best S-curve
- 50 hash-functions ( $r=5, b=10$ )

Green area: False Positive rate
Blue area: False Negative rate

## LSH Summary

- Tune $\boldsymbol{M}, \boldsymbol{b}, r$ to get almost all pairs with similar signatures, but eliminate most pairs that do not have similar signatures
- Check in main memory that candidate pairs really do have similar signatures
- Optional: In another pass through data, check that the remaining candidate pairs really represent similar documents

## Summary: 3 Steps

- Shingling: Convert documents to sets
- We used hashing to assign each shingle an ID
- Min-Hashing: Convert large sets to short signatures, while preserving similarity
- We used similarity preserving hashing to generate signatures with property $\operatorname{Pr}\left[h_{\pi}\left(\mathrm{C}_{1}\right)=h_{\pi}\left(\mathrm{C}_{2}\right)\right]=\operatorname{sim}\left(\mathrm{C}_{1}, \mathrm{C}_{2}\right)$
- We used hashing to get around generating random permutations
- Locality-Sensitive Hashing: Focus on pairs of signatures likely to be from similar documents
- We used hashing to find candidate pairs of similarity $\geq \mathbf{s}$
