Most of the slides are from the Mining of Massive Datasets book. These slides have been modified for CS425. The original slides can be accessed at: www.mmds.org
Some Problems with PageRank

- **Measures generic popularity of a page**
  - Will ignore/miss topic-specific authorities
  - **Solution:** Topic-Specific PageRank (next)

- **Susceptible to Link spam**
  - Artificial link topographies created in order to boost page rank
  - **Solution:** TrustRank

- **Uses a single measure of importance**
  - Other models of importance
  - **Solution:** Hubs-and-Authorities
Topic-Specific PageRank
Instead of generic popularity, can we measure popularity within a topic?

**Goal:** Evaluate Web pages not just according to their popularity, but by how close they are to a particular topic, e.g. “sports” or “history”

Allows search queries to be answered based on interests of the user

**Example:** Query “Trojan” wants different pages depending on whether you are interested in sports, history and computer security
Random walker has a small probability of teleporting at any step

Teleport can go to:
  - **Standard PageRank**: Any page with equal probability
    - To avoid dead-end and spider-trap problems
  - **Topic Specific PageRank**: A topic-specific set of “relevant” pages (teleport set)

Idea: Bias the random walk
  - When walker teleports, she pick a page from a set $S$
  - $S$ contains only pages that are relevant to the topic
    - E.g., Open Directory (DMOZ) pages for a given topic/query
  - For each teleport set $S$, we get a different vector $r_s$
To make this work all we need is to update the teleportation part of the PageRank formulation:

\[
A_{ij} = \begin{cases} 
\beta M_{ij} + (1 - \beta)/|S| & \text{if } i \in S \\
\beta M_{ij} + 0 & \text{otherwise}
\end{cases}
\]

- \( A \) is stochastic!
- We weighted all pages in the teleport set \( S \) equally
  - Could also assign different weights to pages!
- Compute as for regular PageRank:
  - Multiply by \( M \), then add a vector
  - Maintains sparseness
Suppose $S = \{1\}, \beta = 0.8$

<table>
<thead>
<tr>

</tbody>
</table>

S={1,2,3,4}, $\beta=0.8$:  
$r=[0.13, 0.10, 0.39, 0.36]$

S={1,2,3}, $\beta=0.8$:  
$r=[0.17, 0.13, 0.38, 0.30]$

S={1,2}, $\beta=0.8$:  
$r=[0.26, 0.20, 0.29, 0.23]$

S={1}, $\beta=0.8$:  
$r=[0.29, 0.11, 0.32, 0.26]$

S={1}, $\beta=0.90$:  
$r=[0.17, 0.07, 0.40, 0.36]$

S={1}, $\beta=0.70$:  
$r=[0.39, 0.14, 0.27, 0.19]$
Discovering the Topic Vector S

- **Create different PageRanks for different topics**
  - The 16 DMOZ top-level categories:
    - arts, business, sports,...
- **Which topic ranking to use?**
  - User can pick from a menu
  - Classify query into a topic
  - Can use the context of the query
    - E.g., query is launched from a web page talking about a known topic
    - History of queries e.g., “basketball” followed by “Jordan”
  - User context, e.g., user’s bookmarks, ...
Application to Measuring Proximity in Graphs
Proximity on Graphs

a.k.a.: Relevance, Closeness, ‘Similarity’…

[Tong-Faloutsos, ‘06]
Good proximity measure?

- **Shortest path is not good:**

  - No effect of degree-1 nodes (E, F, G)!
  - Multi-faceted relationships
What is good notion of proximity?

- Multiple connections
- Quality of connection
  - Direct & Indirect connections
  - Length, Degree, Weight...

SimRank: Idea

- **SimRank**: Random walks from a **fixed node**

- **Topic Specific PageRank**
  from node $u$: teleport set $S = \{u\}$

- Resulting scores measures similarity to node $u$

- **Problem:**
  - Must be done once for each node $u$
  - Suitable for sub-Web-scale applications
Q: What is most related conference to ICDM?

A: Topic-Specific PageRank with teleport set $S=\{\text{ICDM}\}$
SimRank: Example

ICDM
KDD
SDM
ECML
PKDD
PAKDD
CIKM
DMKD
SIGMOD
ICML
ICDE

0.005
0.004
0.004
PageRank: Summary

- **“Normal” PageRank:**
  - Teleports uniformly at random to any node
  - All nodes have the same probability of surfer landing there: \( S = [0.1, 0.1, 0.1, 0.1, 0.1, 0.1, 0.1, 0.1, 0.1, 0.1] \)

- **Topic-Specific PageRank** also known as **Personalized PageRank:**
  - Teleports to a topic specific set of pages
  - Nodes can have different probabilities of surfer landing there: \( S = [0.1, 0, 0, 0.2, 0, 0, 0.5, 0, 0, 0.2] \)

- **Random Walk with Restarts:**
  - Topic-Specific PageRank where teleport is always to the same node. \( S = [0, 0, 0, 0, 1, 0, 0, 0, 0, 0, 0] \)
TrustRank: Combating the Web Spam
What is Web Spam?

- **Spamming:**
  - Any deliberate action to boost a web page’s position in search engine results, incommensurate with page’s real value

- **Spam:**
  - Web pages that are the result of spamming
  - This is a very broad definition
    - **SEO** industry might disagree!
    - **SEO** = search engine optimization

- Approximately **10-15%** of web pages are spam
Early search engines:
- Crawl the Web
- Index pages by the words they contained
- Respond to search queries (lists of words) with the pages containing those words

Early page ranking:
- Attempt to order pages matching a search query by “importance”

First search engines considered:
- (1) Number of times query words appeared
- (2) Prominence of word position, e.g. title, header
As people began to use search engines to find things on the Web, those with commercial interests tried to exploit search engines to bring people to their own site – whether they wanted to be there or not.

**Example:**
- Shirt-seller might pretend to be about “movies”

**Techniques for achieving high relevance/importance for a web page**
How do you make your page appear to be about movies?

1. Add the word movie 1,000 times to your page
2. Set text color to the background color, so only search engines would see it
3. Or, run the query “movie” on your target search engine
4. See what page came first in the listings
5. Copy it into your page, make it “invisible”

These and similar techniques are term spam
Google’s Solution to Term Spam

- Believe what people say about you, rather than what you say about yourself
  - Use words in the anchor text (words that appear underlined to represent the link) and its surrounding text
- PageRank as a tool to measure the “importance” of Web pages
Our hypothetical shirt-seller loses

- Saying he is about movies doesn’t help, because others don’t say he is about movies
- His page isn’t very important, so it won’t be ranked high for shirts or movies

Example:

- Shirt-seller creates 1,000 pages, each links to his with “movie” in the anchor text
- These pages have no links in, so they get little PageRank
- So the shirt-seller can’t beat truly important movie pages, like IMDB
Why it does not work?

SPAM FARMING
Once Google became the dominant search engine, spammers began to work out ways to fool Google

**Spam farms** were developed to concentrate PageRank on a single page

**Link spam:**
- Creating link structures that boost PageRank of a particular page
Three kinds of web pages from a spammer’s point of view

- Inaccessible pages
- Accessible pages
  - e.g., blog comments pages
  - spammer can post links to his pages
- Owned pages
  - Completely controlled by spammer
  - May span multiple domain names
Spammer’s goal:
- Maximize the PageRank of target page $t$

Technique:
- Get as many links from accessible pages as possible to target page $t$
- Construct “link farm” to get PageRank multiplier effect
One of the most common and effective organizations for a link farm
**Analysis**

- **x**: PageRank contributed by accessible pages
- **y**: PageRank of target page \( t \)
- Rank of each “farm” page: \( \frac{\beta y}{M} + \frac{1-\beta}{N} \)

\[
y = x + \beta M \left[ \frac{\beta y}{M} + \frac{1-\beta}{N} \right] + \frac{1-\beta}{N}
\]

\[
y = x + \beta^2 y + \frac{\beta (1-\beta) M}{N} + \frac{1-\beta}{N}
\]

Very small; ignore

Now we solve for \( y \)

\[
y = \frac{x}{1-\beta^2} + c \frac{M}{N}
\]

where \( c = \frac{\beta}{1+B} \)
\[ y = \frac{x}{1-\beta^2} + c \frac{M}{N} \quad \text{where} \quad c = \frac{\beta}{1+\beta} \]

- For \( \beta = 0.85 \), \( 1/(1-\beta^2) = 3.6 \)

- Multiplier effect for acquired PageRank

- By making \( M \) large, we can make \( y \) as large as we want
TrustRank: Combating the Web Spam
Combating Spam

- **Combating term spam**
  - Analyze text using statistical methods
  - Similar to email spam filtering
  - Also useful: Detecting approximate duplicate pages

- **Combating link spam**
  - Detection and blacklisting of structures that look like spam farms
    - Leads to another war – hiding and detecting spam farms
  - TrustRank = topic-specific PageRank with a teleport set of trusted pages
Basic principle: **Approximate isolation**
- It is rare for a “good” page to point to a “bad” (spam) page

- Sample a set of **seed pages** from the web and “propagate” trust from them.
Picking the Seed Set

- Two conflicting considerations:
  - Human has to inspect each seed page, so seed set must be as small as possible
  - Must ensure every good page gets adequate trust rank, so need make all good pages reachable from seed set by short paths
Suppose we want to pick a seed set of $k$ pages

**How to do that?**

1. **PageRank:**
   - Pick the top $k$ pages by PageRank
   - Theory is that you can’t get a bad page’s rank really high

2. **Use trusted domains** whose membership is controlled, like .edu, .mil, .gov
Call the subset of seed pages that are identified as good the trusted pages

Perform a topic-sensitive PageRank with teleport set = trusted pages

- Propagate trust through links:
  - Each page gets a trust value between 0 and 1
Why is it a good idea?

- **Trust attenuation:**
  - The degree of trust conferred by a trusted page decreases with the distance in the graph.

- **Trust splitting:**
  - The larger the number of out-links from a page, the less scrutiny the page author gives each out-link.
  - Trust is **split** across out-links.
Categorize Spam Pages after TrustRank

- **Solution 1:** Use a threshold value and mark all pages below the trust threshold as spam

- **Solution 2:** Spam Mass
In the TrustRank model, we start with good pages and propagate trust.

Complementary view:
What fraction of a page’s PageRank comes from spam pages?

In practice, we don’t know all the spam pages, so we need to estimate.
Solution 2:

- $r_p$ = PageRank of page $p$
- $r_p^+$ = PageRank of $p$ with teleport into trusted pages only

Then: What fraction of a page’s PageRank comes from spam pages?

$$r_p^- = r_p - r_p^+$$

Spam mass of $p = \frac{r_p^-}{r_p}$

- Pages with high spam mass are spam.
HITS: Hubs and Authorities
Hubs and Authorities

- **HITS (Hypertext-Induced Topic Selection)**
  - Is a measure of importance of pages or documents, similar to PageRank
  - Proposed at around same time as PageRank (‘98)
- **Goal**: Say we want to find good newspapers
  - Don’t just find newspapers. Find “experts” – people who link in a coordinated way to good newspapers
- **Idea**: Links as votes
  - Page is more important if it has more links
    - In-coming links? Out-going links?
Finding newspapers

- **Hubs and Authorities**
  - Each page has 2 scores:
    - Quality as an expert (**hub**):
      - Total sum of votes of authorities pointed to
    - Quality as a content (**authority**):
      - Total sum of votes coming from experts

- **Principle of repeated improvement**

Interesting pages fall into two classes:

1. **Authorities** are pages containing useful information
   - Newspaper home pages
   - Course home pages
   - Home pages of auto manufacturers

2. **Hubs** are pages that link to authorities
   - List of newspapers
   - Course bulletin
   - List of US auto manufacturers
Each page starts with hub score 1. Authorities collect their votes

(Note this is idealized example. In reality graph is not bipartite and each page has both the hub and authority score)
Counting in-links: Authority

Each page starts with hub score 1. Authorities collect their votes

(Note this is idealized example. In reality graph is not bipartite and each page has both the hub and authority score)

Expert Quality: Hub

Sum of authority scores of nodes that the node points to.

(Note this is idealized example. In reality graph is not bipartite and each page has both the hub and authority score)

Hubs collect authority scores

Reweighting

Authorities again collect the hub scores

(Note this is idealized example. In reality graph is not bipartite and each page has both the hub and authority score)
Normalization

- The hub and authority scores can keep on increasing.

- Need normalization after each step.

- Examples:
  - Sum of scores = 1
  - Max score = 1
  - Sum of square scores = 1

- Unlike PageRank, the scores don’t correspond to probabilities.
Mutually Recursive Definition

- A good hub links to many good authorities
- A good authority is linked from many good hubs
- Model using two scores for each node:
  - Hub score and Authority score
  - Represented as vectors $h$ and $a$
Hubs and Authorities

- Each page $i$ has 2 scores:
  - Authority score: $a_i$
  - Hub score: $h_i$

**HITS algorithm:**
- Initialize: $a_j^{(0)} = 1/\sqrt{N}$, $h_j^{(0)} = 1/\sqrt{N}$
- Then keep iterating until convergence:
  - $\forall i$: Authority: $a_i^{(t+1)} = \sum_{j \rightarrow i} h_j^{(t)}$
  - $\forall i$: Hub: $h_i^{(t+1)} = \sum_{i \rightarrow j} a_j^{(t)}$
  - $\forall i$: Normalize:
    $$\sum_i \left(a_i^{(t+1)}\right)^2 = 1, \sum_j \left(h_j^{(t+1)}\right)^2 = 1$$

Hubs and Authorities

- HITS converges to a single stable point
- Notation:
  - Vector $\mathbf{a} = (a_1 \ldots, a_n)$, $\mathbf{h} = (h_1 \ldots, h_n)$
  - Adjacency matrix $\mathbf{A}$ ($N \times N$): $A_{ij} = 1$ if $i \rightarrow j$, 0 otherwise

- Similar to PageRank’s $M^T$ matrix except the entries are all 1s
Hubs and Authorities

- Then \( h_i = \sum_{i \rightarrow j} a_j \)
  can be rewritten as \( h_i = \sum_j A_{ij} \cdot a_j \)
  So: \( h = A \cdot a \)

- Similarly, \( a_i = \sum_{j \rightarrow i} h_j \)
  can be rewritten as \( a_i = \sum_j A_{ji} \cdot h_j = A^T \cdot h \)
Hubs and Authorities

- **HITS algorithm in vector notation:**
  - Set: \( a_i = h_i = \frac{1}{\sqrt{n}} \)
  - Repeat until convergence:
    - \( h = A \cdot a \)
    - \( a = A^T \cdot h \)
    - Normalize \( a \) and \( h \)
  - Then: \( a = A^T \cdot (A \cdot a) \)

Convergence criterion:
\[
\sum_i (h_i^{(t)} - h_i^{(t-1)})^2 < \varepsilon \\
\sum_i (a_i^{(t)} - a_i^{(t-1)})^2 < \varepsilon
\]

\( a \) is updated (in 2 steps):
\[
 a = A^T (A \cdot a) = (A^T A) \cdot a
\]

\( h \) is updated (in 2 steps):
\[
 h = A (A^T h) = (A A^T) \cdot h
\]

Repeated matrix powering

Under reasonable assumptions about $A$, HITS converges to vectors $h^*$ and $a^*$:

- $h^*$ is the principal eigenvector of matrix $AA^T$
- $a^*$ is the principal eigenvector of matrix $A^TA$
Example of HITS

\[
A = \begin{bmatrix}
1 & 1 & 1 \\
1 & 0 & 1 \\
0 & 1 & 0
\end{bmatrix}
\quad A^T = \begin{bmatrix}
1 & 1 & 0 \\
1 & 0 & 1 \\
1 & 1 & 0
\end{bmatrix}
\]

\[
\begin{align*}
\text{h(yahoo)} &= .58 \quad .80 \quad .80 \quad .79 \quad \ldots \quad .788 \\
\text{h(amazon)} &= .58 \quad .53 \quad .53 \quad .57 \quad \ldots \quad .577 \\
\text{h(m’soft)} &= .58 \quad .27 \quad .27 \quad .23 \quad \ldots \quad .211 \\
\end{align*}
\]

\[
\begin{align*}
\text{a(yahoo)} &= .58 \quad .58 \quad .62 \quad .62 \quad \ldots \quad .628 \\
\text{a(amazon)} &= .58 \quad .58 \quad .49 \quad .49 \quad \ldots \quad .459 \\
\text{a(m’soft)} &= .58 \quad .58 \quad .62 \quad .62 \quad \ldots \quad .628 \\
\end{align*}
\]
PageRank and HITS are two solutions to the same problem:

- What is the value of an in-link from $u$ to $v$?
- In the PageRank model, the value of the link depends on the links into $u$.
- In the HITS model, it depends on the value of the other links out of $u$.

The destinies of PageRank and HITS post-1998 were very different.
