- Edge detection is the process of finding meaningful transitions in an image.
- The points where sharp changes in the brightness occur typically form the border between different objects or scene parts.
- These points can be detected by computing intensity differences in local image regions.
- Initial stages of mammalian vision systems also involve detection of edges and local features.

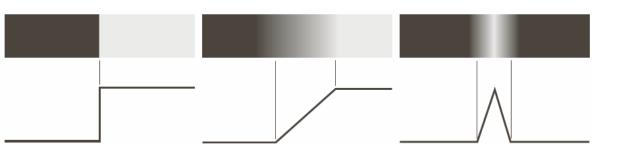

- Sharp changes in the image brightness occur at:
 - Object boundaries
 - A light object may lie on a dark background or a dark object may lie on a light background.
 - Reflectance changes
 - May have quite different characteristics zebras have stripes, and leopards have spots.
 - Cast shadows
 - Sharp changes in surface orientation
- Further processing of edges into lines, curves and circular arcs result in useful features for matching and recognition.

- Basic idea: look for a neighborhood with strong signs of change.
- Problems:
 - Neighborhood size
 - How to detect change

81	82	26	24
		25	
81	82	26	24

- Differential operators:
 - Attempt to approximate the gradient at a pixel via masks.
 - Threshold the gradient to select the edge pixels.

Edge models

a b c

FIGURE 10.8

From left to right, models (ideal representations) of a step, a ramp, and a roof edge, and their corresponding intensity profiles.

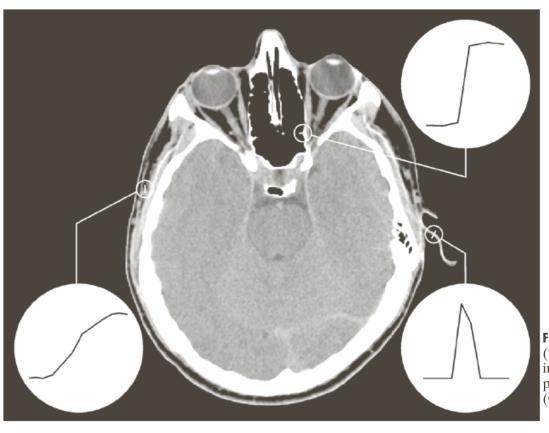

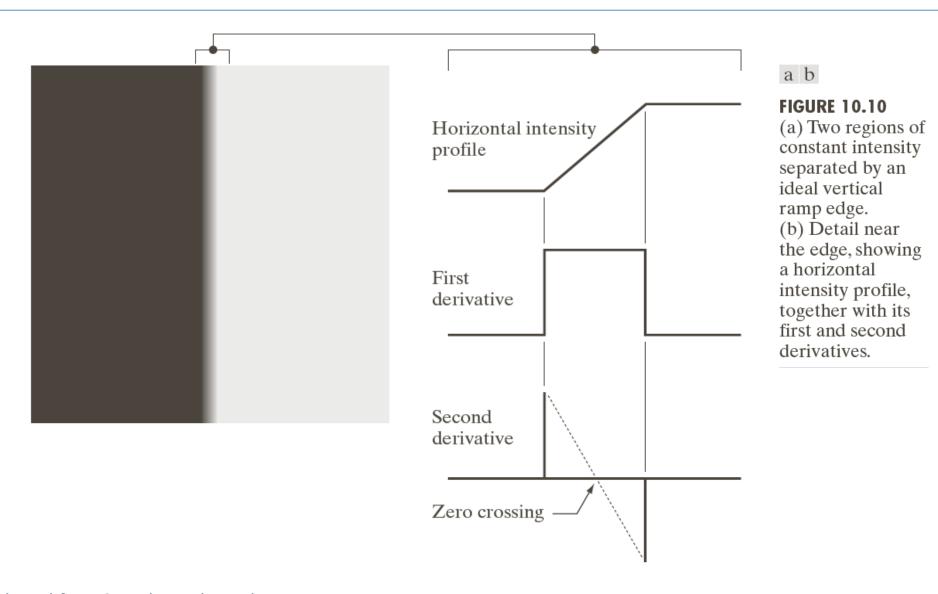

FIGURE 10.9 A 1508×1970 image showing (zoomed) actual ramp (bottom, left), step (top, right), and roof edge profiles. The profiles are from dark to light, in the areas indicated by the short line segments shown in the small circles. The ramp and "step" profiles span 9 pixels and 2 pixels, respectively. The base of the roof edge is 3 pixels. (Original image courtesy of Dr. David R. Pickens, Vanderbilt University.)

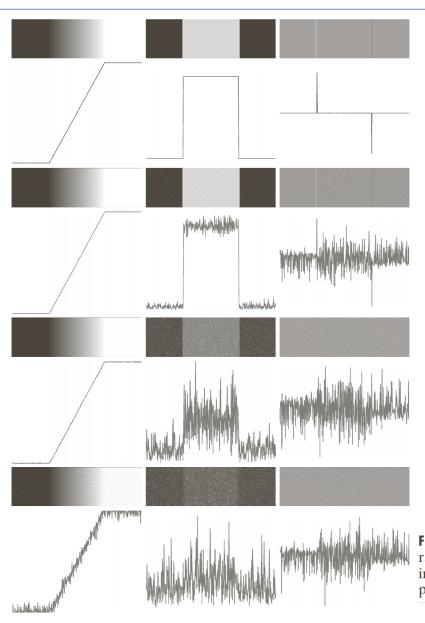

FIGURE 10.11 First column: Images and intensity profiles of a ramp edge corrupted by random Gaussian noise of zero mean and standard deviations of 0.0, 0.1, 1.0, and 10.0 intensity levels, respectively. Second column: First-derivative images and intensity profiles. Third column: Second-derivative images and intensity profiles.

- Three fundamental steps in edge detection:
 - 1. Image smoothing: to reduce the effects of noise.
 - 2. Detection of edge points: to find all image points that are potential candidates to become edge points.
 - 3. Edge localization: to select from the candidate edge points only the points that are true members of an edge.

Observations

- Properties of derivative masks:
 - Coordinates of derivative masks have opposite signs in order to obtain a high response in signal regions of high contrast.
 - The sum of coordinates of derivative masks is zero so that a zero response is obtained on constant regions.
 - First derivative masks produce high absolute values at points of high contrast.
 - Second derivative masks produce zero-crossings at points of high contrast.

Smoothing operators for 1D

S_4	\otimes	M	12	12	12	15	18	15	12	12	12	12

(d) S_4 is a bright impulse or "line"

Figure 5.13: (Top two rows) Smoothing of step and impulse with box mask [1/3, 1/3, 1/3] (bottom two rows) smoothing of step and impulse with Gaussian mask [1/4, 1/2, 1/4].

Observations

- Properties of smoothing masks:
 - Coordinates of smoothing masks are positive and sum to one so that output on constant regions is the same as the input.
 - The amount of smoothing and noise reduction is proportional to the mask size.
 - Step edges are blurred in proportion to the mask size.

- Contrast in the 2D picture function f(x,y) can occur in any direction.
- From calculus, we know that the maximum change occurs along the direction of the gradient.
- The gradient of an image f(x,y) at location (x,y) is defined as the vector

$$\nabla f = \left[\frac{\partial f}{\partial x} \frac{\partial f}{\partial y} \right]^T.$$

The magnitude of the gradient

$$|\nabla f| = \left(\left(\frac{\partial f}{\partial x} \right)^2 + \left(\frac{\partial f}{\partial y} \right)^2 \right)^{1/2}$$

gives the maximum rate of increase of f(x,y) per unit distance in the direction of ∇f .

• The direction of the gradient

$$\angle(\nabla f) = \tan^{-1}\left(\frac{\partial f}{\partial y} / \frac{\partial f}{\partial x}\right)$$

represents the direction of this change with respect to the x-axis.

(b) Thresholded version of the image in Fig. 10.18(d), obtained using a threshold equal to 33% of the highest value in that image.

- We can smooth the image using a Gaussian filter and then compute the derivative.
- Two convolutions: one to smooth, then another one to differentiate?
 - → Actually, no we can use a derivative of Gaussian filter because differentiation is convolution and convolution is associative.

Derivative of Gaussian

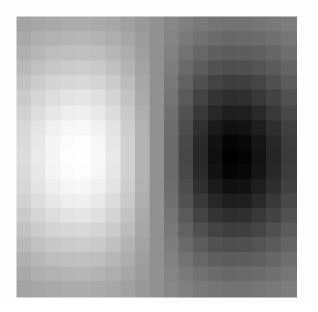

$$D_{x} \otimes (G \otimes I) = (D_{x} \otimes G) \otimes I$$

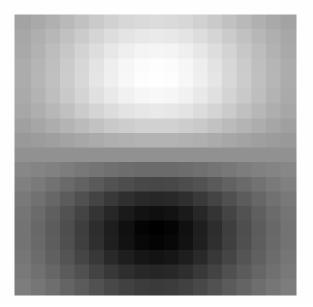

Derivative of Gaussian

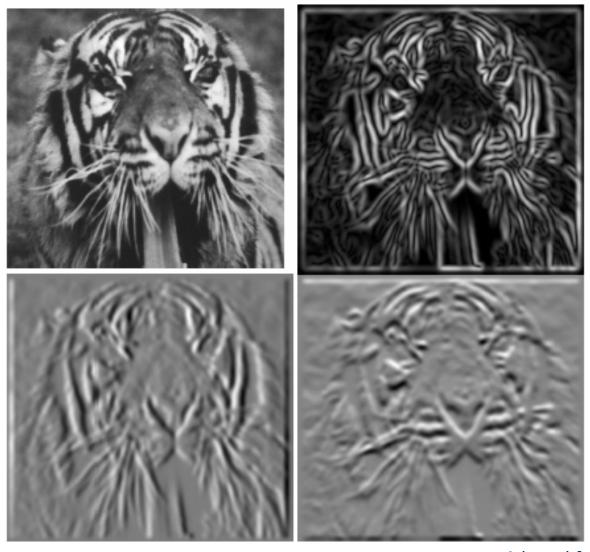

$$D_{x} \otimes (G \otimes I) = (D_{x} \otimes G) \otimes I$$

Derivative of Gaussian

Applying the first derivative of Gaussian

• The *Laplacian* of a 2D function f(x,y) is a second-order derivative defined as

$$\nabla^2 f = \frac{\partial^2 f}{\partial x^2} + \frac{\partial^2 f}{\partial y^2}.$$

- The Laplacian generally is not used in its original form for edge detection because:
 - It is sensitive to noise.
 - Its magnitude produces double edges.
 - ▶ It is unable to detect edge direction.
- However, its zero-crossing property can be used for edge localization.

25

1D Gaussian function:

$$g(x) = \frac{1}{\sqrt{2\pi}\sigma} e^{-\frac{x^2}{2\sigma^2}}.$$

Derivative of Gaussian (DoG):

$$g'(x) = \frac{-x}{\sigma^2}g(x).$$

Laplacian of Gaussian (LoG):

$$g''(x) = \left(\frac{x^2}{\sigma^4} - \frac{-1}{\sigma^2}\right) g(x).$$

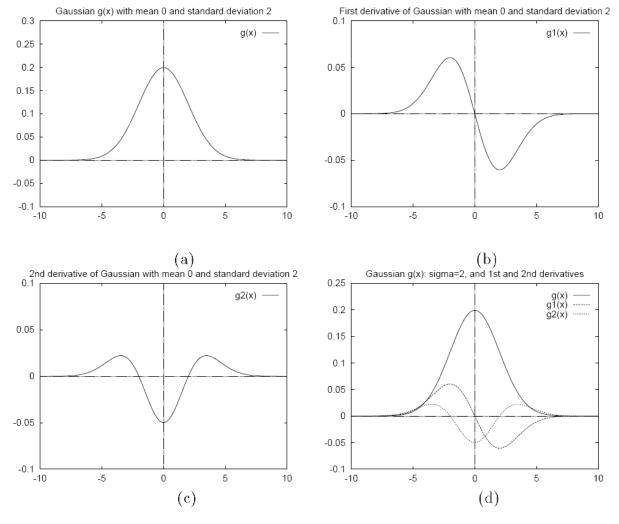

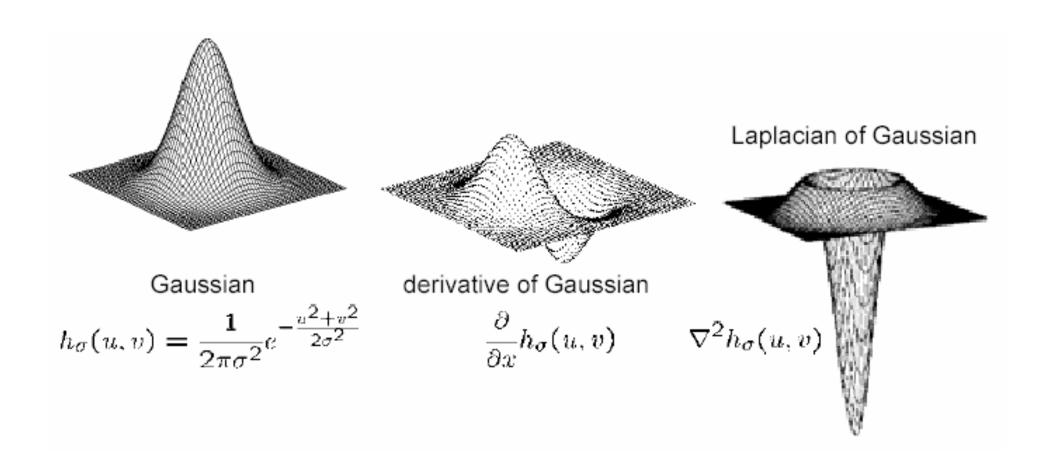

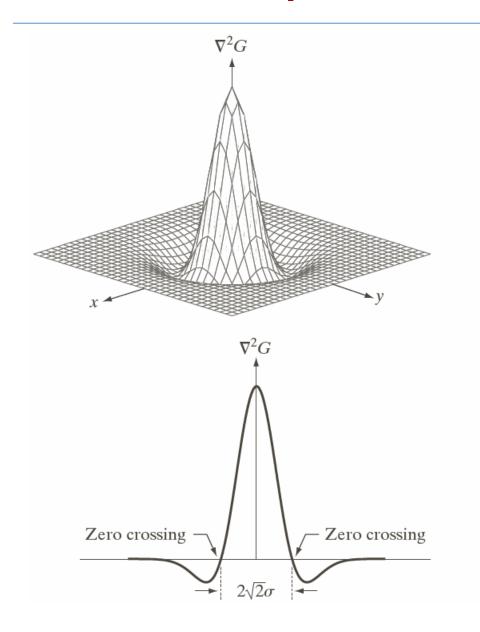

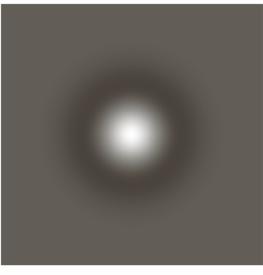

Figure 5.19: (a) Gaussian g(x) with spread $\sigma = 2$; (b) first derivative g'(x); (c) second derivative g''(x), which looks like the cross section of a sombrero upside down from how it would be worn; (d) all three plots superimposed to show how the extreme slopes of g(x) align with the extremas of g'(x) and the zero crossings of g''(x).

Marr/Hildreth edge detector

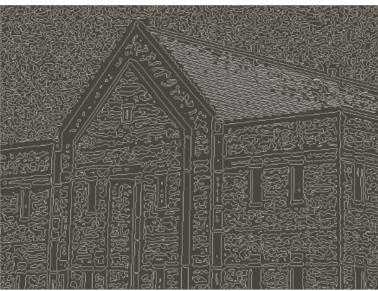

- 1. First smooth the image via a Gaussian convolution.
- 2. Apply a Laplacian filter (estimate 2nd derivative).
- 3. Find zero crossings of the Laplacian of the Gaussian.

This can be done at multiple scales by varying σ in the Gaussian filter.

Marr/Hildreth edge detector

a b c d

FIGURE 10.22

(a) Original image of size 834×1114 pixels, with intensity values scaled to the range [0, 1]. (b) Results of Steps 1 and 2 of the Marr-Hildreth algorithm using $\sigma = 4$ and n = 25. (c) Zero crossings of (b) using a threshold of 0 (note the closedloop edges). (d) Zero crossings found using a threshold equal to 4% of the maximum value of the image in (b). Note the thin edges.

Haralick edge detector

- Fit the gray-tone intensity surface to a piecewise cubic polynomial approximation.
- Use the approximation to find zero crossings of the second directional derivative in the direction that maximizes the first directional derivative.

The derivatives here are calculated from direct mathematical expressions with respect to the cubic polynomial.

Canny edge detector

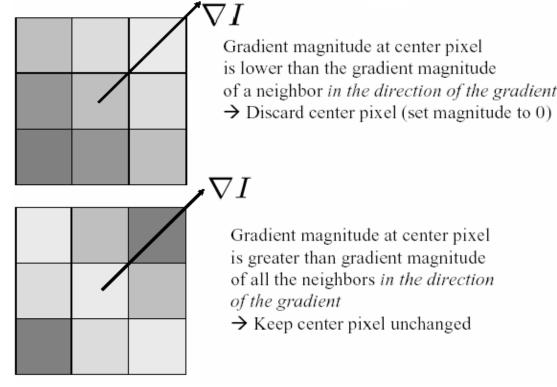

- Canny defined three objectives for edge detection:
 - 1. Low error rate: All edges should be found and there should be no spurious responses.
 - 2. Edge points should be well localized: The edges located must be as close as possible to the true edges.
 - 3. Single edge point response: The detector should return only one point for each true edge point. That is, the number of local maxima around the true edge should be minimum.

Canny edge detector

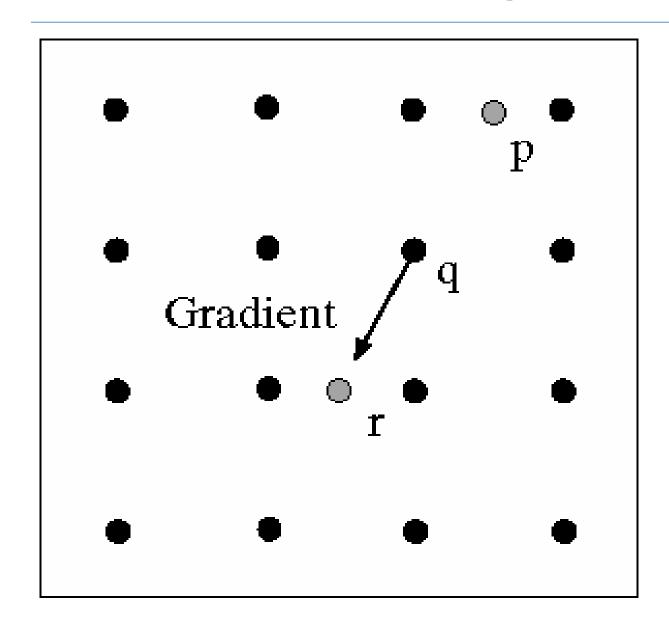

- 1. Smooth the image with a Gaussian filter with spread σ .
- 2. Compute gradient magnitude and direction at each pixel of the smoothed image.
- 3. Zero out any pixel response less than or equal to the two neighboring pixels on either side of it, along the direction of the gradient (non-maxima suppression).
- 4. Track high-magnitude contours using thresholding (hysteresis thresholding).
- 5. Keep only pixels along these contours, so weak little segments go away.

Non-maxima suppression:

- Gradient direction is used to thin edges by suppressing any pixel response that is not higher than the two neighboring pixels on either side of it along the direction of the gradient.
- This operation can be used with any edge operator when thin boundaries are wanted.

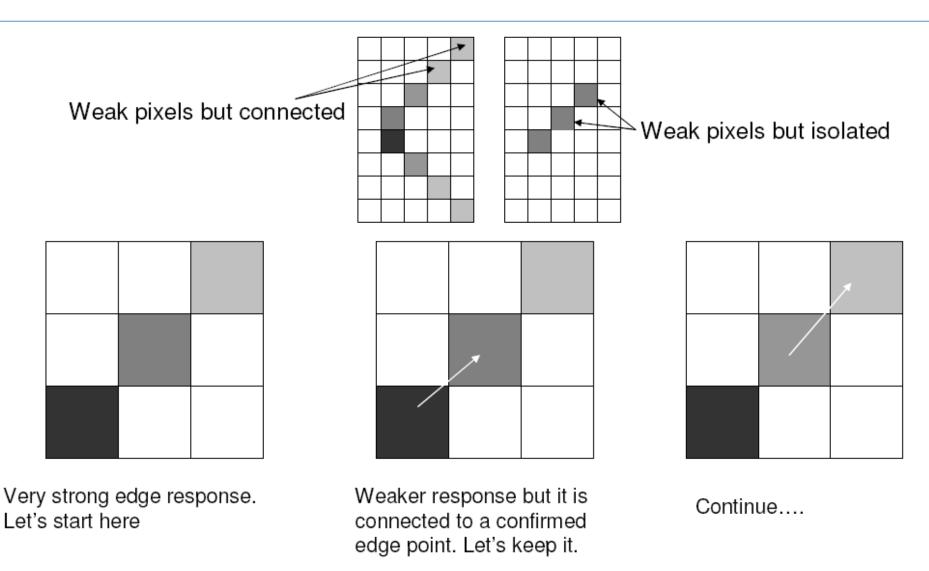

Note: Brighter squares illustrate stronger edge response.

At q, we have a maximum if the value is larger than those at both p and at r. Interpolate to get these values.

- Hysteresis thresholding:
 - Once the gradient magnitudes are thinned, high magnitude contours are tracked.
 - In the final aggregation phase, continuous contour segments are sequentially followed.
 - Contour following is initiated only on edge pixels where the gradient magnitude meets a high threshold.
 - However, once started, a contour may be followed through pixels whose gradient magnitude meet a lower threshold (usually about half of the higher starting threshold).

Note: Darker squares illustrate stronger edge response (larger M)

1. Compute x and y derivatives of image

$$I_x = G_\sigma^x * I \quad I_y = G_\sigma^y * I$$

Compute magnitude of gradient at every pixel

$$M(x,y) = |\nabla I| = \sqrt{I_x^2 + I_y^2}$$

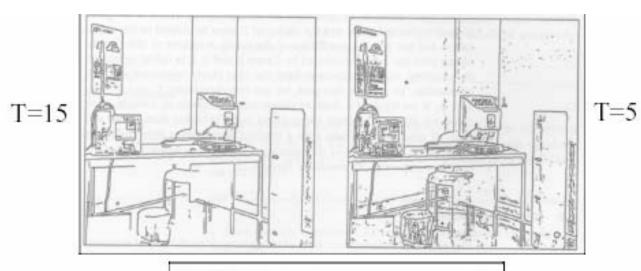

- Eliminate those pixels that are not local maxima of the magnitude in the direction of the gradient
- 4. Hysteresis Thresholding
 - Select the pixels such that $M>T_h$ (high threshold)

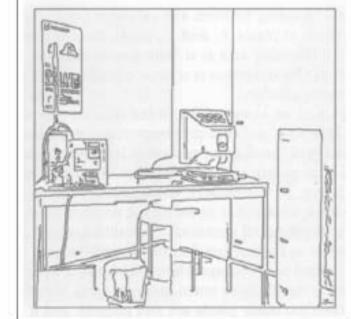

Adapted from Martial Hebert, CMU

ullet Collect the pixels such that $M>T_l$ (low threshold) that are neighbors of already collected edge points

- The Canny operator gives single-pixel-wide images with good continuation between adjacent pixels.
- It is the most widely used edge operator today; no one has done better since it came out in the late 80s. Many implementations are available.
- It is very sensitive to its parameters, which need to be adjusted for different application domains.

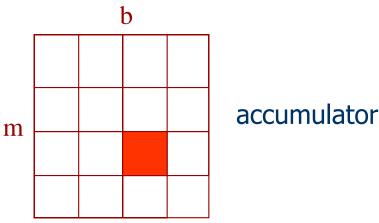

Edge linking

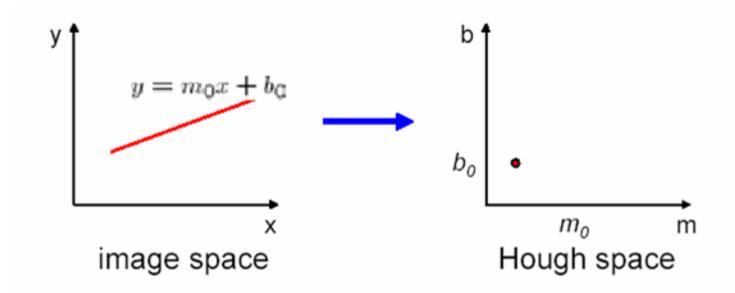

- Hough transform
 - Finding line segments
 - Finding circles
- Model fitting
 - Fitting line segments
 - Fitting ellipses
- Edge tracking

Hough transform

- The Hough transform is a method for detecting lines or curves specified by a parametric function.
- If the parameters are p₁, p₂, ... p_n, then the Hough procedure uses an n-dimensional accumulator array in which it accumulates votes for the correct parameters of the lines or curves found on the image.

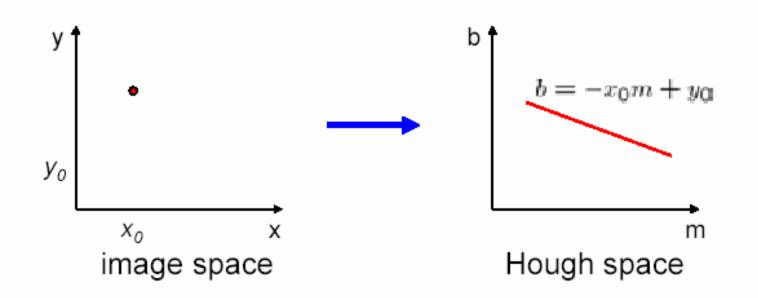

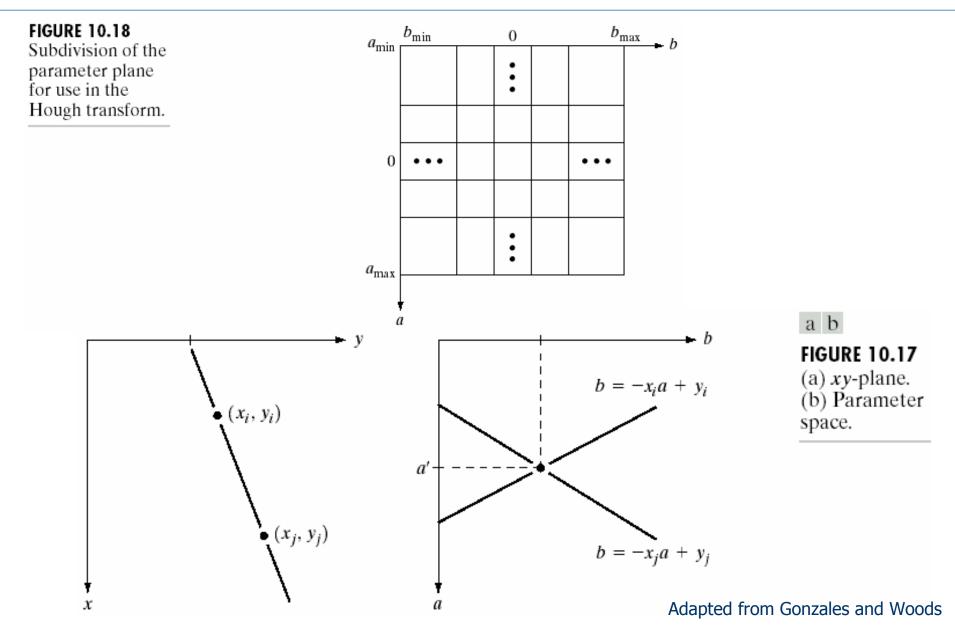

Connection between image (x,y) and Hough (m,b) spaces

- A line in the image corresponds to a point in Hough space
- To go from image space to Hough space:
 - given a set of points (x,y), find all (m,b) such that y = mx + b

Connection between image (x,y) and Hough (m,b) spaces

- · A line in the image corresponds to a point in Hough space
- To go from image space to Hough space:
 - given a set of points (x,y), find all (m,b) such that y = mx + b
- What does a point (x₀, y₀) in the image space map to?
 - A: the solutions of b = -x₀m + y₀
 - this is a line in Hough space

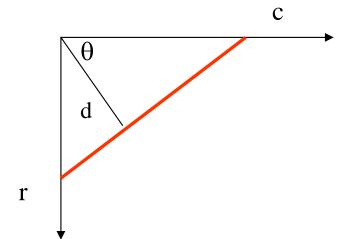

CS 484, Spring 2008

- y = mx + b is not suitable (why?)
- The equation generally used is:

$$d = r \sin(\theta) + c \cos(\theta)$$
.

d is the distance from the line to origin.

 θ is the angle the perpendicular makes with the column axis.

```
Accumulate the straight line segments in gray-tone image S to accumulator A.
S[R, C] is the input gray-tone image.
NLINES is the number of rows in the image.
NPIXELS is the number of pixels per row.
A[DQ, THETAQ] is the accumulator array.
DQ is the quantized distance from a line to the origin.
THETAQ is the quantized angle of the normal to the line.
     procedure accumulate_lines(S,A);
     A := 0;

Model fitting

- Mathematical models that fit data not only reveal important structure in the data, but also can provide efficient representations for further analysis.
- Mathematical models exist for lines, circles, cylinders, and many other shapes.
- We can use the method of least squares for determining the parameters of the best mathematical model fitting observed data.

CS 484, Spring 2008 ©2008, Selim Aksoy 65

- Given a set of observed points $\{(x_i, y_i), i = 1, \dots, n\}$.
- A straight line can be modeled as a function with two parameters:

$$y = ax + b$$
.

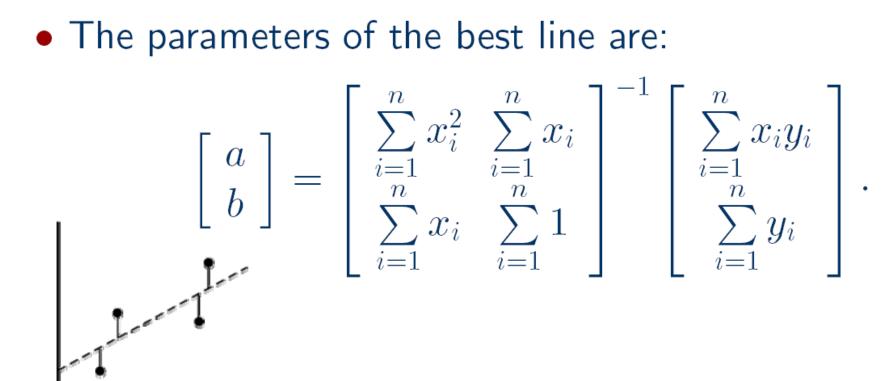

• To measure how well a model fits a set of n observations can be computed using the *least-squares error criteria*:

$$LSE = \sum_{i=1}^{n} (ax_i + b - y_i)^2$$

where $ax_i + b - y_i$ is the algebraic distance.

 The best model is the model with the paramaters minimizing this criteria.

- For the model y = ax + b, the parameters that minimize LSE can be found by taking partial derivatives and solving for the unknowns.

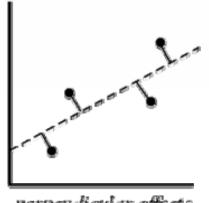

CS 484, Spring 2008

vertical offsets

• If we use the geometric distance where ax + by + c = 0 and $a^2 + b^2 = 1$, the solution for $[a \ b]^T$ is the eigenvector corresponding to the smallest eigenvalue of

$$\begin{bmatrix} \sum_{i=1}^{n} x_i^2 - \left(\sum_{i=1}^{n} x_i\right)^2 & \sum_{i=1}^{n} x_i y_i - \left(\sum_{i=1}^{n} x_i\right) \left(\sum_{i=1}^{n} y_i\right) \\ \sum_{i=1}^{n} x_i y_i - \left(\sum_{i=1}^{n} x_i\right) \left(\sum_{i=1}^{n} y_i\right) & \sum_{i=1}^{n} y_i^2 - \left(\sum_{i=1}^{n} y_i\right)^2 \end{bmatrix}$$

and
$$c = -a \sum_{i=1}^{n} x_i - b \sum_{i=1}^{n} y_i$$
.

perpendicular offsets

- Problems in fitting:
 - Outliers
 - Error definition (algebraic vs. geometric distance)
 - Statistical interpretation of the error (hypothesis testing)
 - Nonlinear optimization
 - High dimensionality (of the data and/or the number of model parameters)
 - Additional fit constraints

Model fitting: ellipses

Fitting a general conic represented by a second-order polynomial

$$ax^2 + bxy + cy^2 + dx + ey + f = 0$$

can be approached by minimizing the sum of squared algebraic distances.

• See Fitzgibbon $et\ al.$ (PAMI 1999) for an algorithm that constrains the parameters so that the conic representation is forced to be an ellipse.

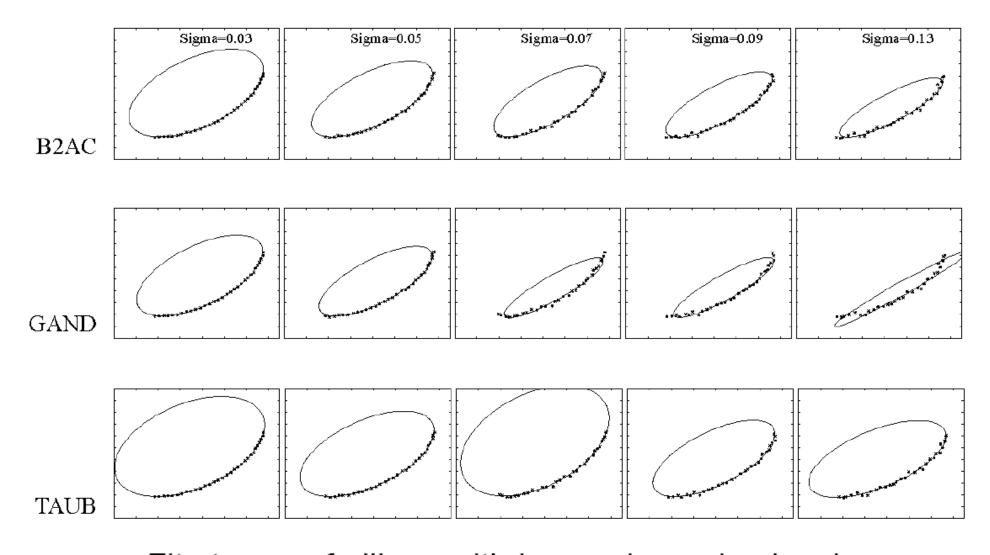

Model fitting: ellipses

```
% x,y are vectors of coordinates
function a=fit_ellipse(x,y)
% Build design matrix
  D = [x.*x x.*y y.*y x y ones(size(x))];
% Build scatter matrix
  S = D'*D;
% Build 6x6 constraint matrix
  C(6,6)=0; C(1,3)=-2; C(2,2)=1; C(3,1)=-2;
% Solve generalised eigensystem
  [gevec, geval] = eig(S,C);
% Find the only negative eigenvalue
  [NegR, NegC] = find(geval<0 & ~isinf(geval));</pre>
% Get fitted parameters
  a = gevec(:,NegC);
```

Algorithm 15.1: Incremental line fitting by walking along a curve, fitting a line to runs of pixels along the curve, and breaking the curve when the residual is too large

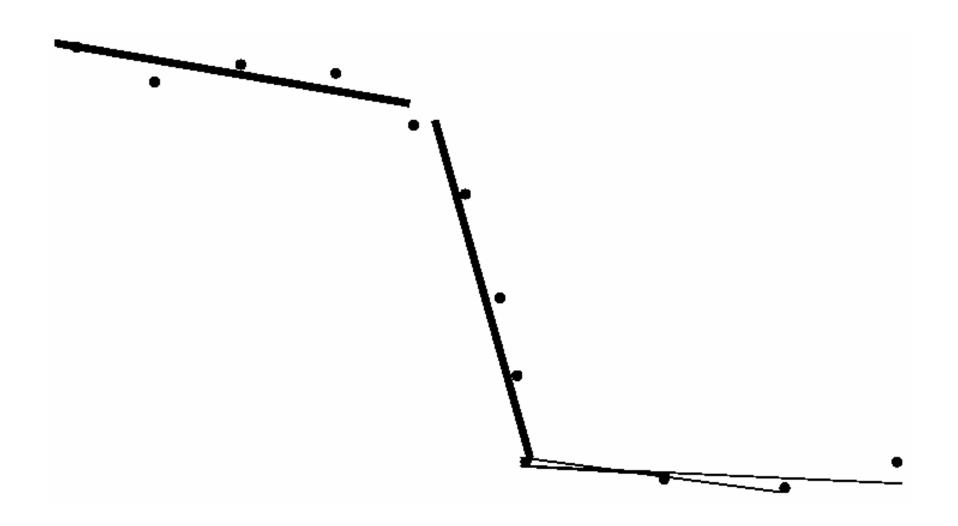

```
Put all points on curve list, in order along the curve
Empty the line point list
Empty the line list
Until there are too few points on the curve
Transfer first few points on the curve to the line point list
Fit line to line point list
While fitted line is good enough
Transfer the next point on the curve
to the line point list and refit the line
end
Transfer last point(s) back to curve
Refit line
Attach line to line list
end
```

Edge tracking

- Mask-based approach uses masks to identify the following events:
 - start of a new segment,
 - interior point continuing a segment,
 - end of a segment,
 - junction between multiple segments,
 - corner that breaks a segment into two.

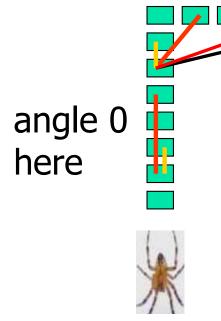

Edge tracking: ORT Toolkit

- Designed by Ata Etemadi.
- The algorithm is called Strider and is like a spider moving along pixel chains of an image, looking for junctions and corners.
- It identifies them by a measure of local asymmetry.
 - When it is moving along a straight or curved segment with no interruptions, its legs are symmetric about its body.
 - When it encounters an obstacle (i.e., a corner or junction) its legs are no longer symmetric.
 - If the obstacle is small (compared to the spider), it soon becomes symmetrical.
 - If the obstacle is large, it will take longer.
- The accuracy depends on the length of the spider and the size of its stride.
 - The larger they are, the less sensitive it becomes.

Edge tracking: ORT Toolkit

The measure of asymmetry is the angle between two line segments.

L1: the line segment from pixel 1 of the spider to pixel N-2 of the spider

L2: the line segment from pixel 1 of the spider to pixel N of the spider

The angle must be <= arctan(2/length(L2))

Longer spiders allow less of an angle.

Edge tracking: ORT Toolkit

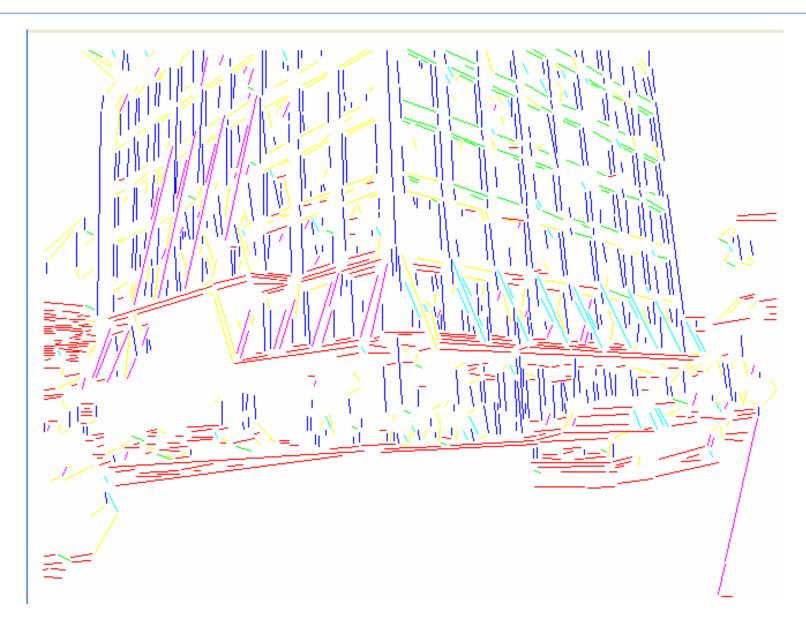

- The parameters are the length of the spider and the number of pixels per step.
- These parameters can be changed to allow for less sensitivity, so that we get longer line segments.
- The algorithm has a final phase in which adjacent segments whose angle differs by less than a given threshold are joined.
- Advantages:
 - Works on pixel chains of arbitrary complexity.
 - Can be implemented in parallel.
 - No assumptions and parameters are well understood.

Example: building detection

- Mauro Costa's dissertation at the University of Washington for recognizing 3D objects having planar, cylindrical, and threaded surfaces:
 - Detects edges from two intensity images.
 - From the edge image, finds a set of high-level features and their relationships.
 - Hypothesizes a 3D model using relational indexing.
 - Estimates the pose of the object using point pairs, line segment pairs, and ellipse/circle pairs.
 - Verifies the model after projecting to 2D.

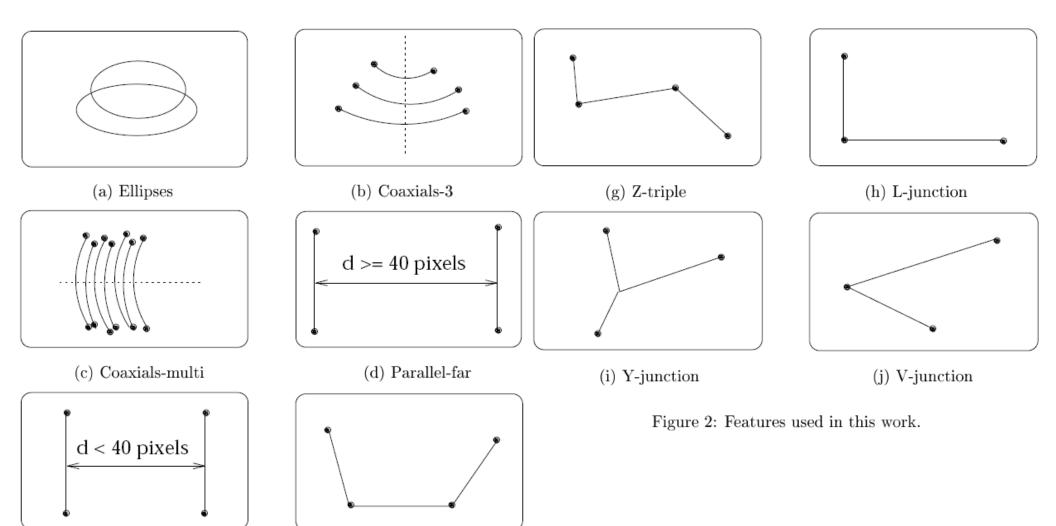

Example scenes used. The labels "left" and "right" indicate the direction of the light source.

- Learning phase: relational indexing by encoding each 2-graph and storing in a hash table.
- Matching phase: voting by each 2-graph observed in the image.

Incorrect hypothesis

- The matched features of the hypothesized object are used to determine its pose.
- 2. The **3D mesh** of the object is used to project all its features onto the image.
- 3. A verification procedure checks how well the object features line up with edges on the image.
