Binary Image Analysis

Selim Aksoy Department of Computer Engineering Bilkent University saksoy@cs.bilkent.edu.tr

Outline

- Introduction to binary image analysis
- Thresholding
- Mathematical morphology
- Pixels and neighborhoods
- Connected components analysis

Binary image analysis

- Binary image analysis consists of a set of operations that are used to produce or process binary images, usually images of 0's and 1's where
 - 0 represents the background,
 - 1 represents the foreground.

Application areas

Document analysis

Industrial inspection

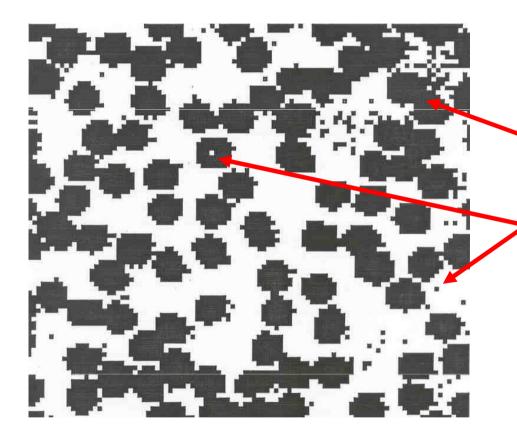

Adapted from Shapiro and Stockman

CS 484, Spring 2011

Operations

- Separate objects from background and from one another.
- Aggregate pixels for each object.
- Compute features for each object.

Example: red blood cell image

Adapted from Linda Shapiro, U of Washington

- Many blood cells are separate objects.
- Many touch each other
 → bad!
- Salt and pepper noise is present.
- How useful is this data?
- 63 separate objects are detected.
- Single cells have area of about 50 pixels.

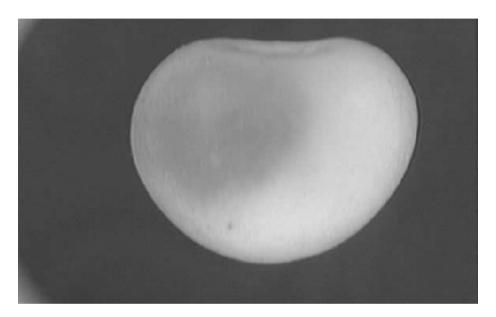

CS 484, Spring 2011

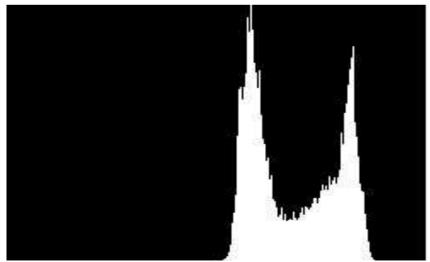

Thresholding

- Binary images can be obtained from gray level images by thresholding.
- Assumptions for thresholding:
 - Object region of interest has intensity distribution different from background.
 - Object pixels likely to be identified by intensity alone:
 - intensity > a
 - intensity < b</p>
 - a < intensity < b</p>
- Works OK with flat-shaded scenes or engineered scenes.
- Does not work well with natural scenes.

Use of histograms for thresholding

- Background is black.
- Healthy cherry is bright.
- Bruise is medium dark.
- Histogram shows two cherry regions (black background has been removed).

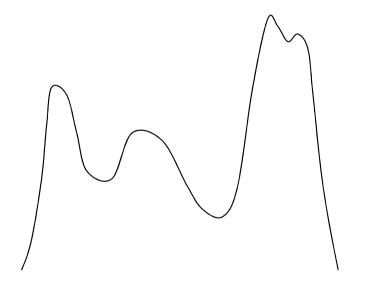

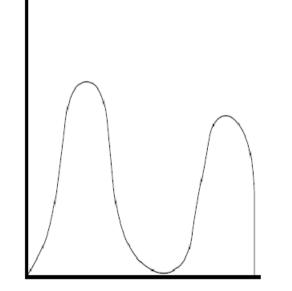

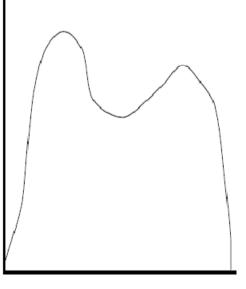

Adapted from Shapiro and Stockman

Automatic thresholding

How can we use a histogram to separate an image into 2 (or several) different regions?

Is there a single clear threshold? 2? 3?

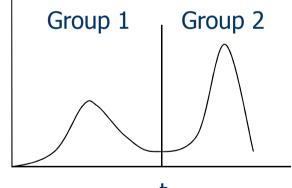

Two distinct modes

Overlapped modes

Adapted from Shapiro and Stockman

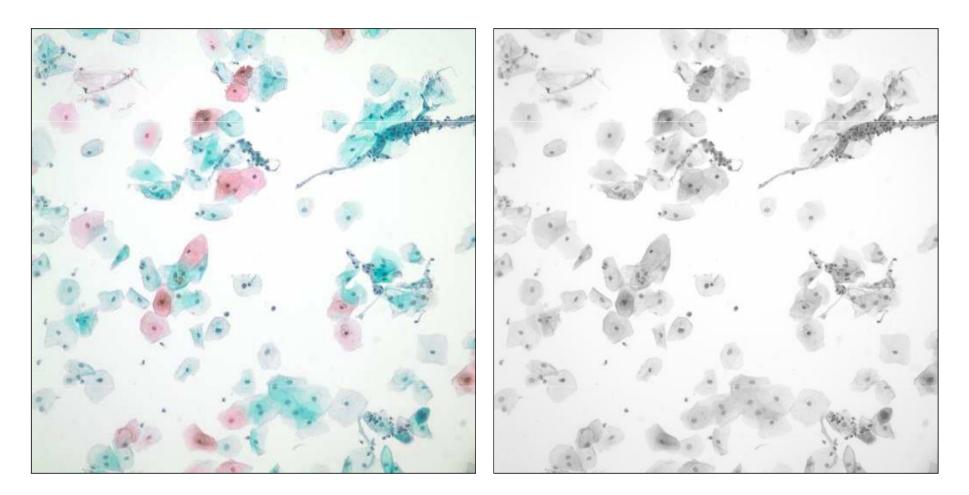

Automatic thresholding: Otsu's method

- Assumption: the histogram is bimodal.
- Method: find the threshold t that minimizes the weighted sum of within-group variances for the two groups that result from separating the gray levels at value t.
- The best threshold t can be determined by a simple sequential search through all possible values of t.

 If the gray levels are strongly dependent on the location within the image, local or dynamic thresholds can also be used.

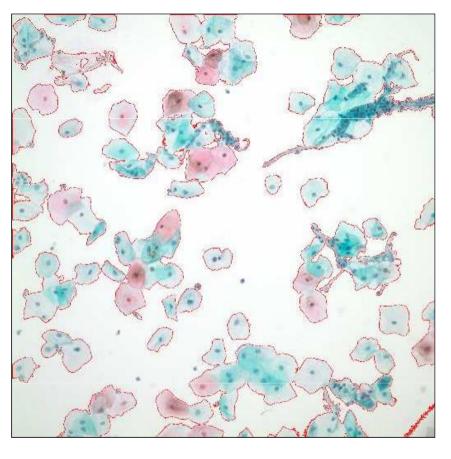

Automatic thresholding

A Pap smear image example: RGB image (left) and grayscale image (right).

Automatic thresholding

Histogram of the negative image (top-left), sum of within-group variances versus the threshold (bottom-left), resulting mask overlayed as red on the original image (top).

Mathematical morphology

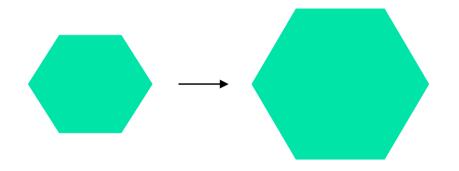

- The word morphology refers to form and structure.
- In computer vision, it is used to refer to the shape of a region.
- The language of mathematical morphology is set theory where sets represent objects in an image.
- We will discuss morphological operations on binary images whose components are sets in the 2D integer space Z².

Mathematical morphology

- Mathematical morphology consists of two basic operations
 - dilation
 - erosion
 - and several composite relations
 - opening
 - closing
 - conditional dilation
 - **•** • •

Dilation

- Dilation expands the connected sets of 1s of a binary image.
- It can be used for
 - growing features

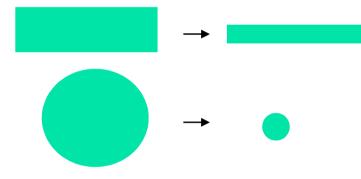

filling holes and gaps

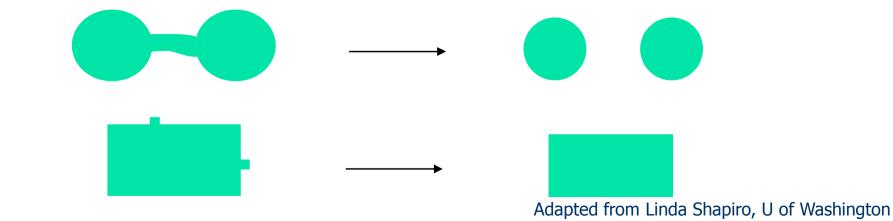

Adapted from Linda Shapiro, U of Washington

Erosion

- Erosion shrinks the connected sets of 1s of a binary image.
- It can be used for
 - shrinking features

removing bridges, branches and small protrusions

CS 484, Spring 2011

Basic concepts from set theory

- Let A be a set in Z². If a = (a₁, a₂) is an element of A, we write a ∈ A; otherwise, we write a ∉ A.
- Set A being a *subset* of set B is denoted by $A \subseteq B$.
- The *union* of two sets A and B is denoted by $A \cup B$.
- The *intersection* of two sets A and B is denoted by $A \cap B$.
- The *complement* of a set A is the set of elements not contained in A:

$$A^c = \{ w | w \notin A \}.$$

The *difference* of two sets A and B, denoted by A − B, is defined as

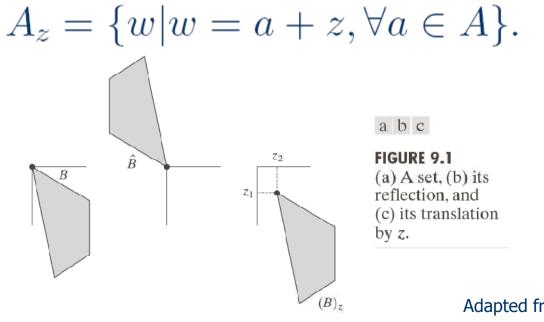

$$A - B = \{w | w \in A, w \notin B\} = A \cap B^c.$$

Basic concepts from set theory

• The *reflection* of set B, denoted by \check{B} , is defined as

$$\check{B} = \{ w | w = -b, \forall b \in B \}.$$

• The *translation* of set A by point $z = (z_1, z_2)$, denoted by A_z , is defined as

Adapted from Gonzales and Woods

Structuring elements

- Structuring elements are small binary images used as shape masks in basic morphological operations.
- They can be any shape and size that is digitally representable.
- One pixel of the structuring element is denoted as its origin.
- Origin is often the central pixel of a symmetric structuring element but may in principle be any chosen pixel.

Structuring elements

$ \begin{array}{c ccccccccccccccccccccccccccccccccccc$	$\begin{array}{c c c c c c c c c c c c c c c c c c c $	$ \begin{array}{c ccccccccccccccccccccccccccccccccccc$
$ \begin{array}{c ccccccccccccccccccccccccccccccccccc$	1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 e) I I I I I I	1 1 1 1
structuring elements. Second row: Structuring elements converted to rectangular arrays. The dots denote the centers of the SEs.		Gonzales and Woods,

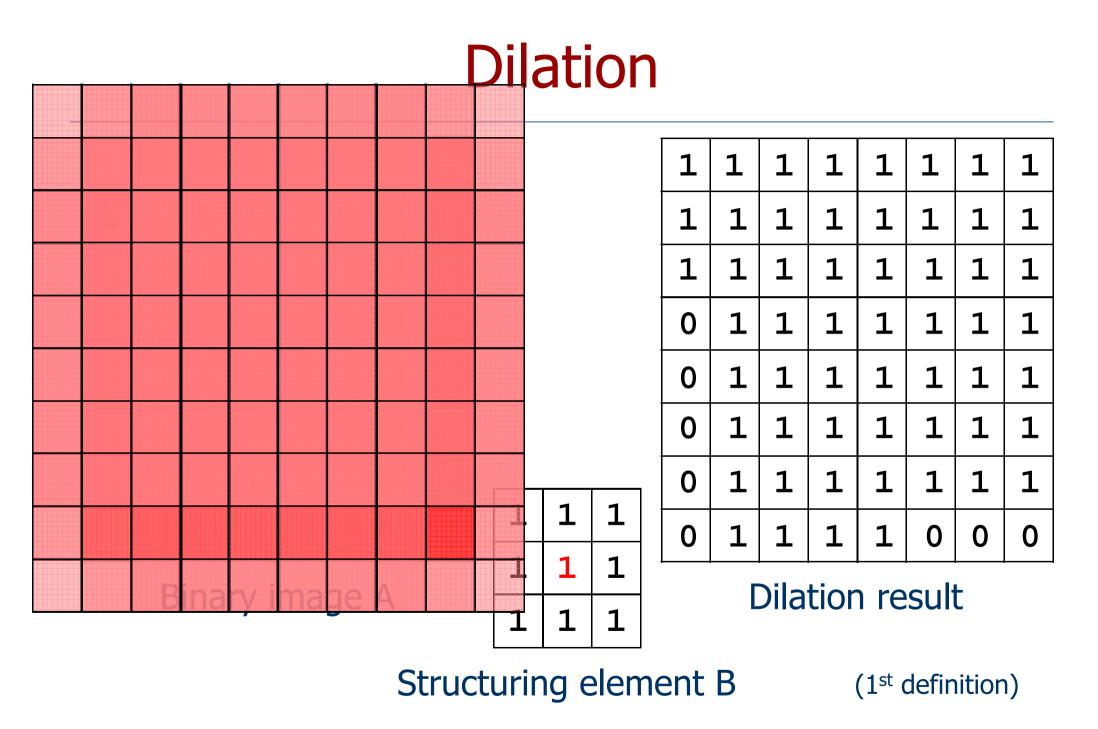

and Shapiro and Stockman

Dilation

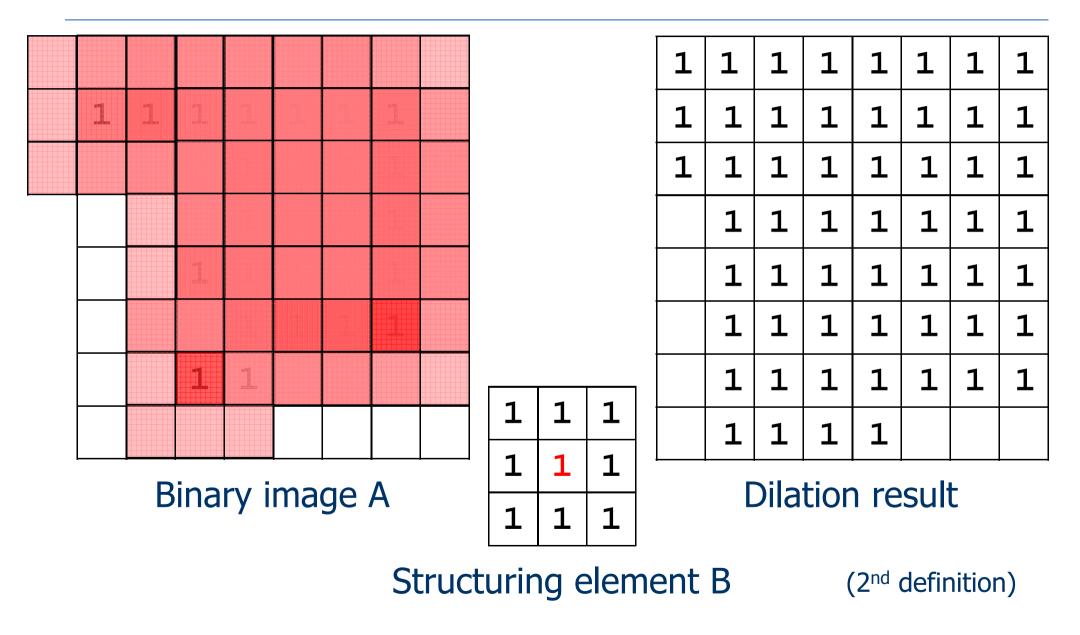

• The *dilation* of binary image A by structuring element B is denoted by $A \oplus B$ and is defined by

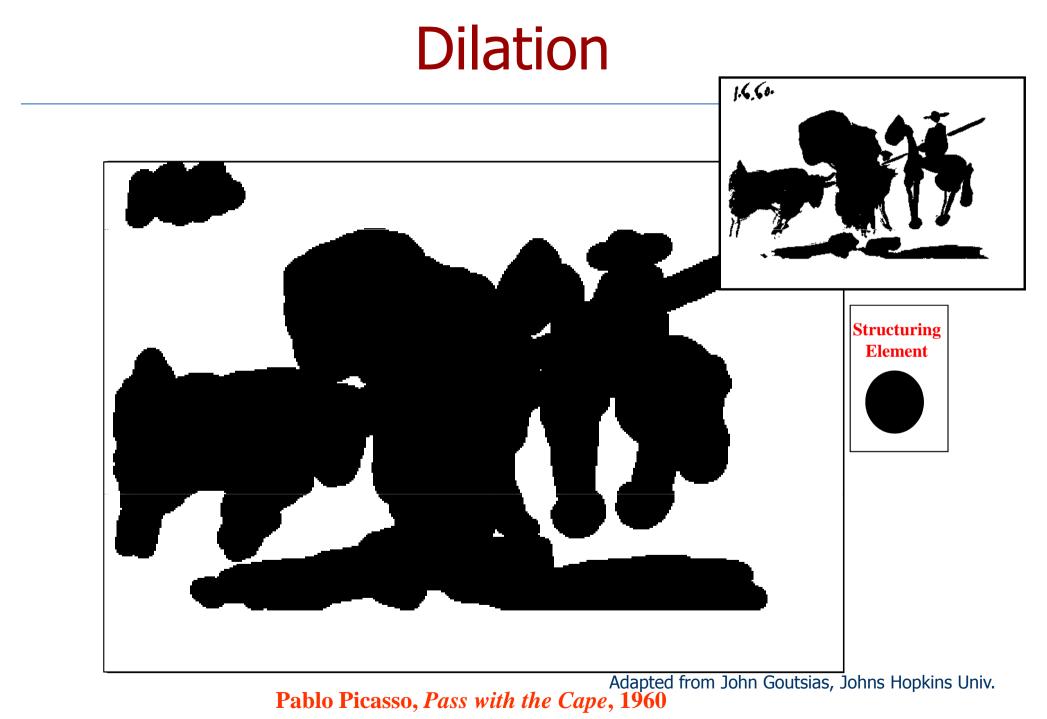

$$A \oplus B = \{ z | \check{B}_z \cap A \neq \emptyset \},\$$
$$= \bigcup_{a \in A} B_a.$$

- First definition: The dilation is the set of all displacements z such that \check{B}_z and A overlap by at least one element.
- Second definition: The structuring element is swept over the image. Each time the origin of the structuring element touches a binary 1-pixel, the entire translated structuring element is ORed to the output image, which was initialized to all zeros.

Dilation

Dilation

Historically, certain computer programs were written using only two digits rather than four to define the applicable year. Accordingly, the company's software may recognize a date using "00" as 1900 rather than the year 2000.

Historically, certain computer programs were written using only two digits rather than four to define the applicable year. Accordingly, the company's software may recognize a date using "00" as 1900 rather than the year 2000.

Erosion

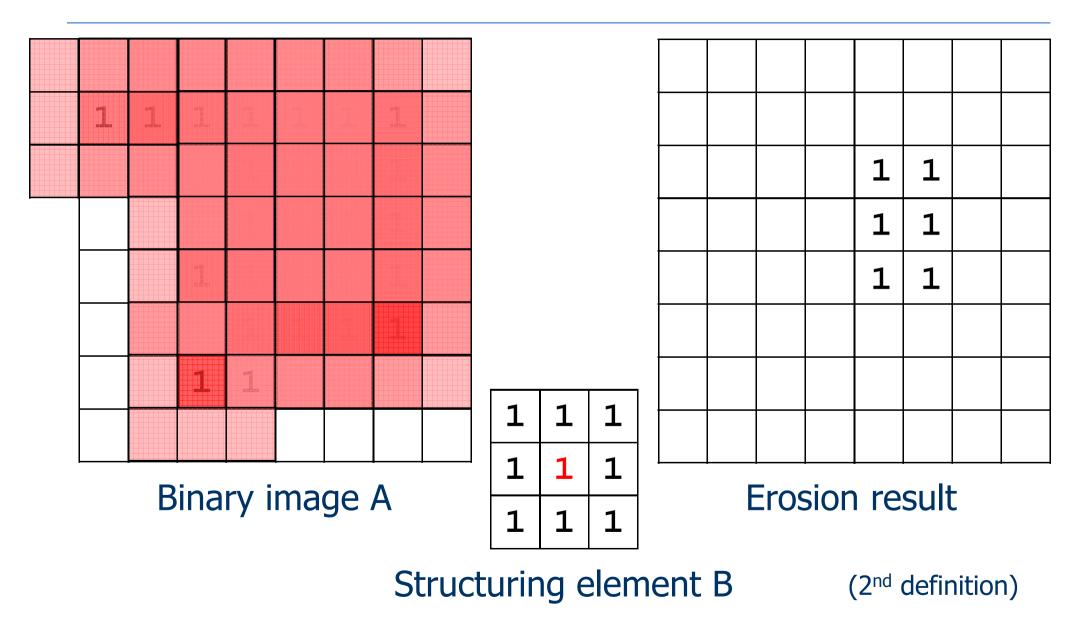

• The *erosion* of binary image A by structuring element B is denoted by $A \ominus B$ and is defined by

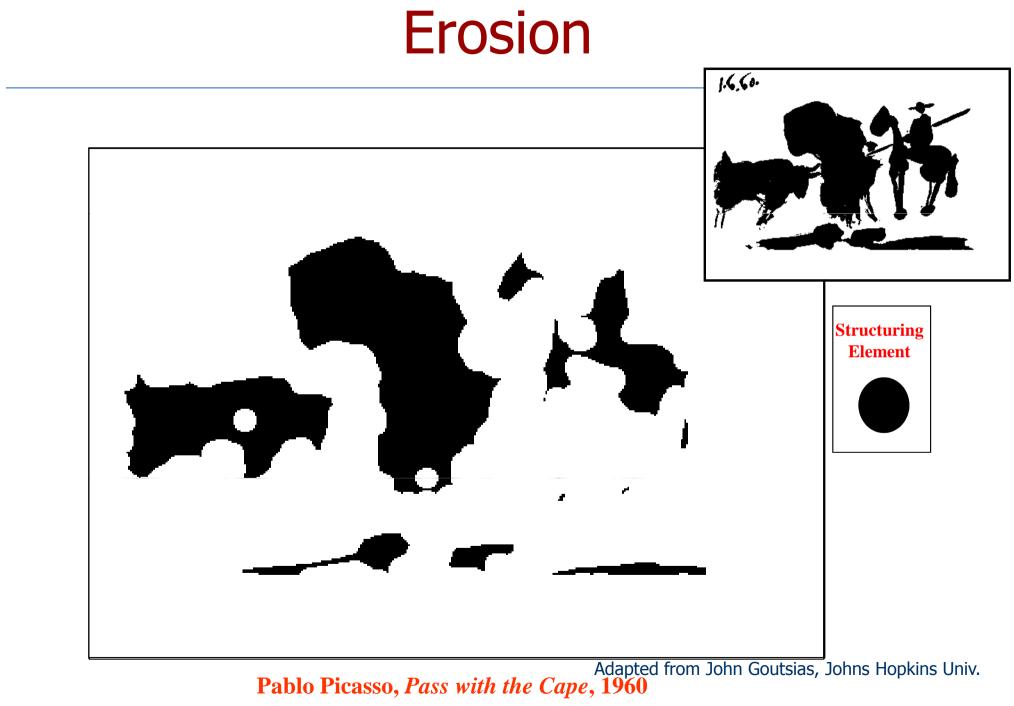

$$A \ominus B = \{ z | B_z \subseteq A \},\$$
$$= \{ a | a + b \in A, \forall b \in B \}.$$

- ► First definition: The erosion is the set of all points z such that B, translated by z, is contained in A.
- Second definition: The structuring element is swept over the image. At each position where every 1-pixel of the structuring element covers a 1-pixel of the binary image, the binary image pixel corresponding to the origin of the structuring element is ORed to the output image.

Opening

• The opening of binary image A by structuring element B is denoted by $A \circ B$ and is defined by

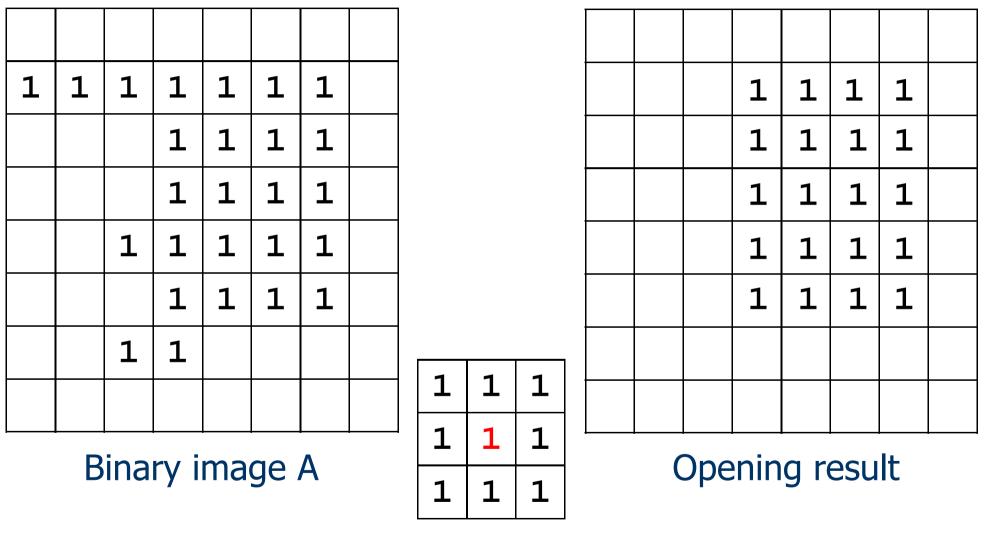

$$A \circ B = (A \ominus B) \oplus B.$$

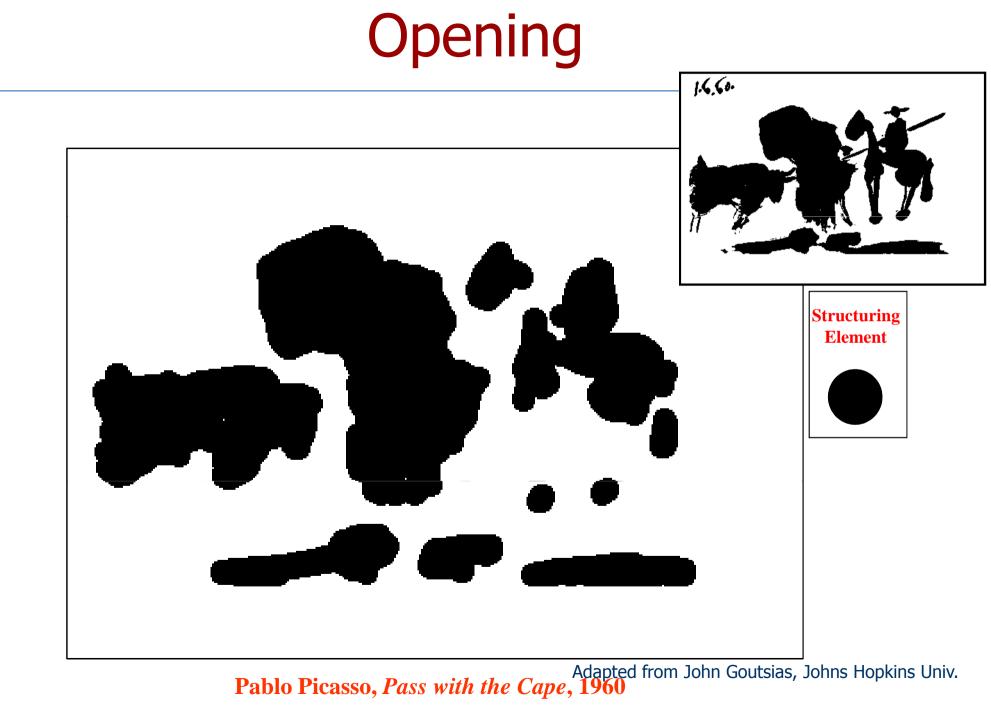

abcd

Opening

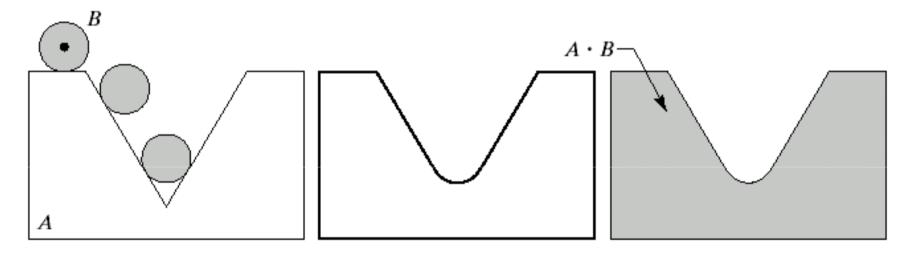

Structuring element B

Closing

• The *closing* of binary image A by structuring element B is denoted by $A \bullet B$ and is defined by

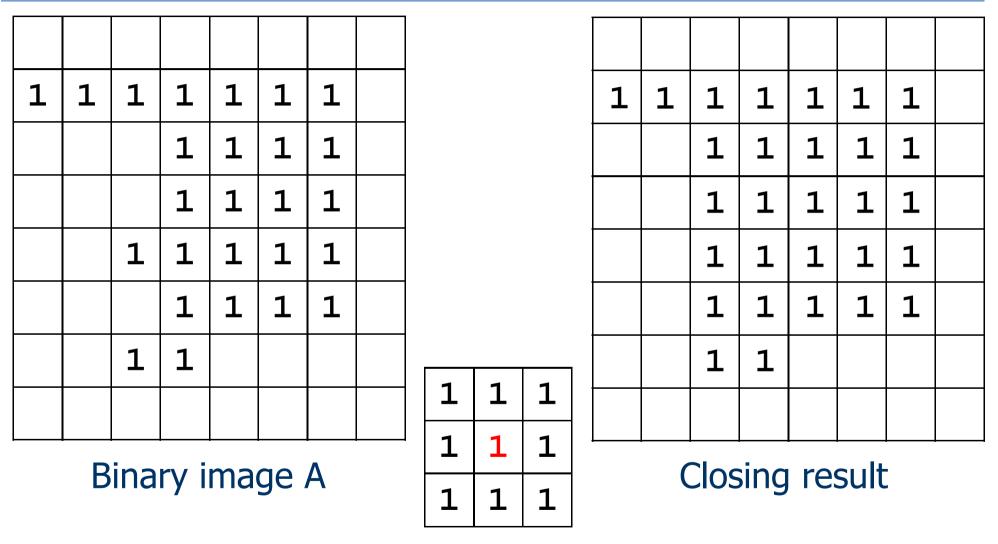

$$A \bullet B = (A \oplus B) \ominus B.$$

Properties

 Dilation and erosion are duals of each other with respect to set complementation and reflection, i.e.,

$$(A \ominus B)^c = A^c \oplus \check{B}.$$

 Opening and closing are duals of each other with respect to set complementation and reflection, i.e.,

$$(A \bullet B)^c = A^c \circ \check{B}.$$

Properties

- Opening satisfies the following properties:
 - $A \circ B$ is a subset of A.
 - If C is a subset of D, then $C \circ B$ is a subset of $D \circ B$.
 - $\blacktriangleright (A \circ B) \circ B = A \circ B.$
- Closing satisfies the following properties:
 - A is a subset of $A \bullet B$.
 - If C is a subset of D, then $C \bullet B$ is a subset of $D \bullet B$.

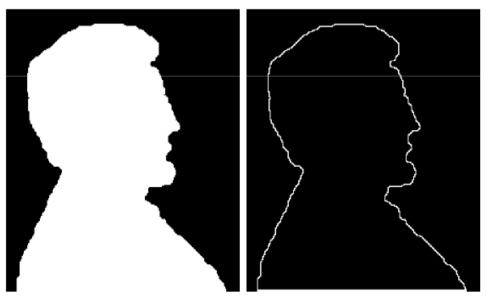

$$\bullet (A \bullet B) \bullet B = A \bullet B.$$

Boundary extraction

• The *boundary* of a set A can be obtained by first eroding A by B and then performing the set difference between A and its erosion, i.e.,

$$\mathsf{boundary}(A) = A - (A \ominus B)$$

where B is a suitable structuring element.

a b

FIGURE 9.14 (a) A simple binary image, with 1's represented in white. (b) Result of using Eq. (9.5-1) with the structuring element in Fig. 9.13(b).

Conditional dilation

 Given an original binary image B, a processed binary image C, and a structuring element A, let C₀ = C and C_n = (C_{n-1} ⊕ A) ∩ B. The conditional dilation of C by A with respect to B is defined by

$$C \oplus |_B A = C_m$$

where the index m is the smallest index satisfying $C_m = C_{m-1}$.

- Given a structuring element that when applied to a binary image
 removes the components that do not satisfy certain shape and
 - size constraints, and
 - leaves a few 1-pixels of those components that do satisfy the constraints,

conditional dilation recovers the latter components using what remains of them after the erosion.

CS 484, Spring 2011

Region filling

 Given set A containing the boundary points of a region, and a point p inside the boundary, the following procedure *fills the region* with 1's:

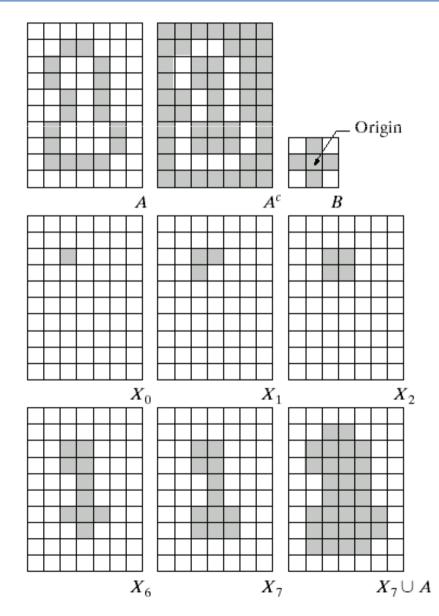

$$X_k = (X_{k-1} \oplus B) \cap A^c, \quad k = 1, 2, 3, \dots$$

- where $X_0 = p$ and B is the cross structuring element. The procedure terminates at iteration step k if $X_k = X_{k-1}$.
- The set union of X_k and A contains the filled set and its boundary.

a b c

FIGURE 9.16 (a) Binary image (the white dot inside one of the regions is the starting point for the region-filling algorithm). (b) Result of filling that region (c) Result of filling all regions.

Hit-or-miss transform

- Let $B = (B_1, B_2)$ denote the set composed of an object and its local background where B_1 is the set formed from elements of B associated with the object and B_2 is the set of elements of B associated with the background.
- \bullet The hit-or-miss transform is denoted by $A \circledast B$ and is defined by

$$A \circledast B = (A \ominus B_1) \cap (A^c \ominus B_2).$$

 The set A ⊛ B contains all the (origin) points at which, simultaneously, B₁ found a match ("hit") in A and B₂ found a match in A^c.

Hit-or-miss transform

Adapted from Gonzales and Woods

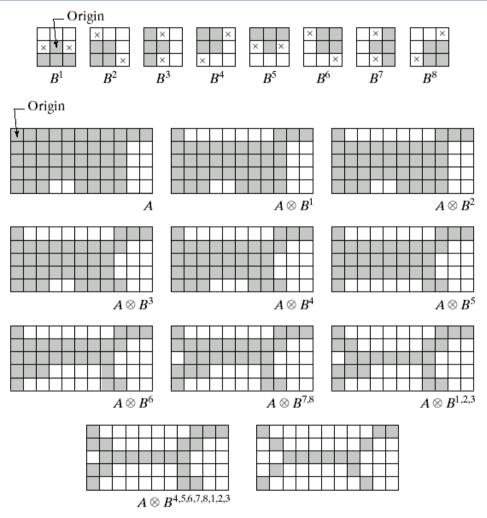

Thinning

 The *thinning* of a set A by a structuring element B, denoted by A ⊗ B, can be defined in terms of the hit-or-miss transform:

$$A \otimes B = A - (A \circledast B)$$
$$= A \cap (A \circledast B)^{c}.$$

 Thinning is done using a sequence of structuring elements where each one is the rotated version of the previous one in the sequence.

Thinning

a bcd efg hij kl **FIGURE 9.21** (a) Sequence of rotated structuring elements used for thinning. (b) Set *A*. (c) Result of thinning with the first element. (d)–(i) Results of thinning with the next seven elements (there was no change between the seventh and eighth elements). (j) Result of using the first element again (there were no changes for the next two elements). (k) Result after convergence. (l) Conversion to *m*-connectivity.

Thickening

Thickening is the morphological dual of thinning and is defined by

$$A \odot B = A \cup (A \circledast B)$$

where B is a structuring element suitable for thickening.

 A sequence of structuring elements of the same form as in thinning but with all 1's and 0's interchanged can be used.

Thickening

Pixels and neighborhoods

- In many algorithms, not only the value of a particular pixel, but also the values of its neighbors are used when processing that pixel.
- The two most common definitions for neighbors are the 4-neighbors and the 8-neighbors of a pixel.

NW	N	NE
W	*	E
SW	S	SE

a) four-neighborhood N_4

b) eight-neighborhood N_8

Figure 3.2: The two most common neighborhoods of a pixel.

CS 484, Spring 2011

Pixels and neighborhoods

• Given pixels $p = (x_1, y_1)$ and $q = (x_2, y_2)$:

▶ The *Euclidean distance* between *p* and *q* is defined as

$$D_e(p,q) = \left((x_1 - x_2)^2 + (y_1 - y_2)^2 \right)^{1/2}$$

The D₄ distance (also called the *city-block distance*) between p and q is defined as

$$D_4(p,q) = |x_1 - x_2| + |y_1 - y_2|.$$

The D₈ distance (also called the *chessboard distance*) between p and q is defined as

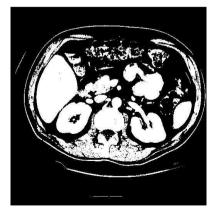

$$D_8(p,q) = \max\{|x_1 - x_2|, |y_1 - y_2|\}.$$

Pixels and neighborhoods

- Once you have a binary image, you can identify and then analyze each connected set of pixels.
- The connected components operation takes in a binary image and produces a labeled image in which each pixel has the integer label of either the background (0) or a component.

CS 484, Spring 2011	} Algorithm 2: Recursive Connec	ted Components 67

- Row-by-row labeling algorithm:
 - The first pass propagates a pixel's label to its neighbors to the right and below it. (Whenever two different labels can propagate to the same pixel, these labels are recorded as an equivalence class.)
 - 2. The second pass performs a translation, assigning to each pixel the label of its equivalence class.
- A union-find data structure is used for efficient construction and manipulation of equivalence classes represented by tree structures.

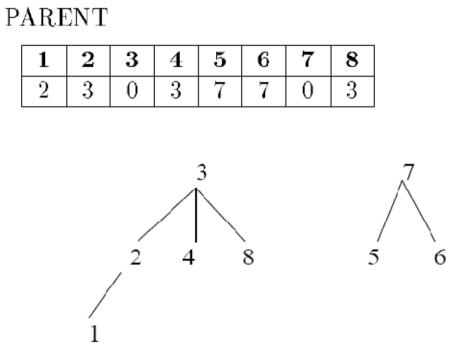

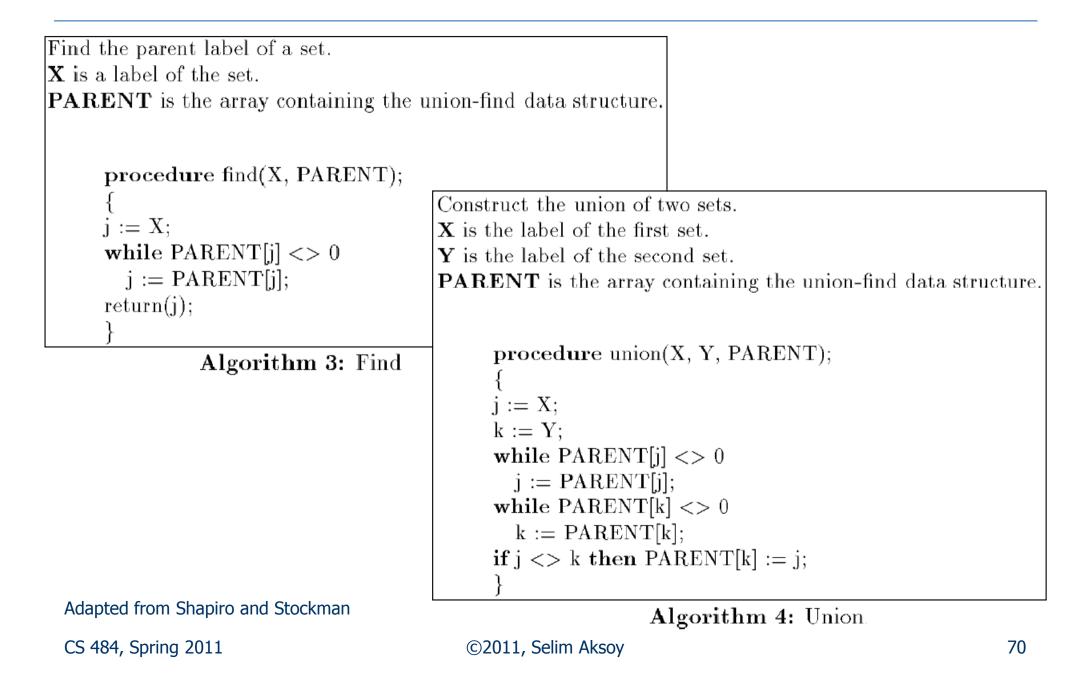

Figure 3.9: The union-find data structure for two sets of labels. The first set contains the labels $\{1,2,3,4,8\}$, and the second set contains labels $\{5,6,7\}$. For each integer label *i*, the value of PARENT[i] is the label of the parent of *i* or zero if *i* is a root node and has no parent.
