

Probabilistic Graphical Models

Part II: Undirected Graphical Models

Introduction

- ▶ We looked at directed graphical models whose structure and parametrization provide a natural representation for many real-world problems.
- ▶ Undirected graphical models are useful where one cannot naturally ascribe a directionality to the interaction between the variables.

Introduction

- ▶ An example model that satisfies:
 - ▶ $(A \perp C | \{B, D\})$
 - ▶ $(B \perp D | \{A, C\})$
 - ▶ No other independencies
- ▶ These independencies cannot be naturally captured in a Bayesian network.

Figure 1: An example undirected graphical model.

An Example

- ▶ Four students are working together in pairs on a homework.
- ▶ Alice and Charles cannot stand each other, and Bob and Debbie had a relationship that ended badly.
- ▶ Only the following pairs meet: Alice and Bob; Bob and Charles; Charles and Debbie; and Debbie and Alice.
- ▶ The professor accidentally misspoke in the class, giving rise to a possible misconception.
- ▶ In study pairs, each student transmits her/his understanding of the problem.

An Example

- ▶ Four binary random variables are defined, representing whether the student has a misconception or not.
- ▶ Assume that for each $X \in \{A, B, C, D\}$, x^1 denotes the case where the student has the misconception, and x^0 denotes the case where she/he does not.
- ▶ Alice and Charles never speak to each other directly, so A and C are conditionally independent given B and D .
- ▶ Similarly, B and D are conditionally independent given A and C .

An Example

(a)

(b)

(c)

Figure 2: Example models for the misconception example. (a) An undirected graph modeling study pairs over four students. (b) An unsuccessful attempt to model the problem using a Bayesian network. (c) Another unsuccessful attempt.

Parametrization

- ▶ How to parametrize this undirected graph?
- ▶ We want to capture the affinities between related variables.
- ▶ Conditional probability distributions cannot be used because they are not symmetric, and the chain rule need not apply.
- ▶ Marginals cannot be used because a product of marginals does not define a consistent joint.
- ▶ A general purpose function: *factor* (also called *potential*).

Parametrization

- ▶ Let $\mathbf{D}$ is a set of random variables.
 - ▶ A factor ϕ is a function from $\text{Val}(\mathbf{D})$ to $\mathbb{R}$.
 - ▶ A factor is nonnegative if all its entries are nonnegative.
 - ▶ The set of variables $\mathbf{D}$ is called the scope of the factor.
- ▶ In the example in Figure 2, an example factor is

$$\phi_1(A, B) : \text{Val}(A, B) \mapsto \mathbb{R}^+.$$

Parametrization

Table 1: Factors for the misconception example.

$\phi_1(A, B)$			$\phi_2(B, C)$			$\phi_3(C, D)$			$\phi_4(D, A)$		
a^0	b^0	30	b^0	c^0	100	c^0	d^0	1	d^0	a^0	100
a^0	b^1	5	b^0	c^1	1	c^0	d^1	100	d^0	a^1	1
a^1	b^0	1	b^1	c^0	1	c^1	d^0	100	d^1	a^0	1
a^1	b^1	10	b^1	c^1	100	c^1	d^1	1	d^1	a^1	100

Parametrization

- ▶ The value associated with a particular assignment a, b denotes the affinity between these two variables: the higher the value $\phi_1(a, b)$, the more compatible these two values are.
- ▶ For ϕ_1 , if A and B disagree, there is less weight.
- ▶ For ϕ_3 , if C and D disagree, there is more weight.
- ▶ A factor is not normalized, i.e., the entries are not necessarily in $[0, 1]$.

Parametrization

- ▶ The Markov network defines the local interactions between directly related variables.
- ▶ To define a global model, we need to combine these interactions.
- ▶ We combine the local models by multiplying them as

$$P(a, b, c, d) = \phi_1(a, b)\phi_2(b, c)\phi_3(c, d)\phi_4(d, a).$$

Parametrization

- ▶ However, there is no guarantee that the result of this process is a normalized joint distribution.
- ▶ Thus, it is normalized as

$$P(a, b, c, d) = \frac{1}{Z} \phi_1(a, b) \phi_2(b, c) \phi_3(c, d) \phi_4(d, a)$$

where

$$Z = \sum_{a,b,c,d} \phi_1(a, b) \phi_2(b, c) \phi_3(c, d) \phi_4(d, a).$$

- ▶ Z is known as the partition function.

Parametrization

Table 2: Joint distribution for the misconception example.

Assignment				Unnormalized	Normalized
a^0	b^0	c^0	d^0	300,000	0.04
a^0	b^0	c^0	d^1	300,000	0.04
a^0	b^0	c^1	d^0	300,000	0.04
a^0	b^0	c^1	d^1	30	4.110^{-6}
a^0	b^1	c^0	d^0	500	6.910^{-5}
a^0	b^1	c^0	d^1	500	6.910^{-5}
a^0	b^1	c^1	d^0	5,000,000	0.69
a^0	b^1	c^1	d^1	500	6.910^{-5}
a^1	b^0	c^0	d^0	100	1.410^{-5}
a^1	b^0	c^0	d^1	1,000,000	0.14
a^1	b^0	c^1	d^0	100	1.410^{-5}
a^1	b^0	c^1	d^1	100	1.410^{-5}
a^1	b^1	c^0	d^0	10	1.410^{-6}
a^1	b^1	c^0	d^1	100,000	0.014
a^1	b^1	c^1	d^0	100,000	0.014
a^1	b^1	c^1	d^1	100,000	0.014

Parametrization

- ▶ There is a tight connection between the factorization of the distribution and its independence properties.
- ▶ For example, $P \models (\mathbf{X} \perp \mathbf{Y} | \mathbf{Z})$ if and only if we can write P in the form $P(\mathcal{X}) = \phi_1(\mathbf{X}, \mathbf{Z})\phi_2(\mathbf{Y}, \mathbf{Z})$.
- ▶ From the example in Figure 2,

$$P(A, B, C, D) = \frac{1}{Z} \phi_1(A, B) \phi_2(B, C) \phi_3(C, D) \phi_4(D, A),$$

we can infer that

$$P \models A \perp C | \{B, D\},$$

$$P \models B \perp D | \{A, C\}.$$

Parametrization

- ▶ Factors do not correspond to either probabilities or to conditional probabilities.
- ▶ It is harder to estimate them from data.
- ▶ One idea for parametrization could be to associate parameters directly with the edges in the graph.
- ▶ This is not sufficient to parametrize a full distribution.

Parametrization

- ▶ A more general representation can be obtained by allowing factors over arbitrary subsets of variables.
- ▶ Let $\mathbf{X}$, $\mathbf{Y}$, and $\mathbf{Z}$ be three disjoint sets of variables, and let $\phi_1(\mathbf{X}, \mathbf{Y})$ and $\phi_2(\mathbf{Y}, \mathbf{Z})$ be two factors.
- ▶ We define the factor product $\phi_1 \times \phi_2$ to be a factor $\psi : \text{Val}(\mathbf{X}, \mathbf{Y}, \mathbf{Z}) \mapsto \mathbb{R}$ as follows:

$$\psi(\mathbf{X}, \mathbf{Y}, \mathbf{Z}) = \phi_1(\mathbf{X}, \mathbf{Y})\phi_2(\mathbf{Y}, \mathbf{Z}).$$

- ▶ The key aspect is the fact that the two factors ϕ_1 and ϕ_2 are multiplied in way that matches up the common part $\mathbf{Y}$.

Parametrization

Figure 3: An example of factor product.

Parametrization

- ▶ Note that the factors are not marginals.
- ▶ In the misconception model, the marginal over A, B is

a^0	b^0	0.13	but the factor is	a^0	b^0	30
a^0	b^1	0.69		a^0	b^1	5
a^1	b^0	0.14		a^1	b^0	1
a^1	b^1	0.04		a^1	b^1	10

- ▶ A factor is only one contribution to the overall joint distribution.
- ▶ The distribution as a whole has to take into consideration the contributions from all of the factors involved.

Gibbs Distributions

- ▶ We can use the more general notion of factor product to define an undirected parametrization of a distribution.
- ▶ A distribution P_{Φ} is a *Gibbs distribution* parametrized by a set of factors $\Phi = \{\phi_1(\mathbf{D}_1), \dots, \phi_K(\mathbf{D}_K)\}$ if it is defined as follows:

$$P_{\Phi}(X_1, \dots, X_n) = \frac{1}{Z} \phi_1(\mathbf{D}_1) \times \dots \times \phi_K(\mathbf{D}_K)$$

where

$$Z = \sum_{X_1, \dots, X_n} \phi_1(\mathbf{D}_1) \times \dots \times \phi_K(\mathbf{D}_K)$$

is the partition function.

- ▶ The $\mathbf{D}_i$ are the scopes of the factors.

Gibbs Distributions

- ▶ If our parametrization contains a factor whose scope contains both X and Y , we would like the associated Markov network structure $\mathcal{H}$ to contain an edge between X and Y .
- ▶ We say that a distribution P_Φ with $\Phi = \{\phi_1(\mathbf{D}_1), \dots, \phi_K(\mathbf{D}_K)\}$ factorizes over a Markov network $\mathcal{H}$ if each $\mathbf{D}_k, k = 1, \dots, K$, is a *complete subgraph* of $\mathcal{H}$.
- ▶ The factors that parametrize a Markov network are often called *clique potentials*.

Gibbs Distributions

- ▶ We can reduce the number of factors by allowing factors only for *maximal cliques*.
- ▶ However, the parametrization using maximal clique potentials generally obscures structure that is present in the original set of factors.

Figure 4: The cliques in two simple Markov networks. (a) $\{A, B\}$, $\{B, C\}$, $\{C, D\}$, and $\{D, A\}$. (b) $\{A, B, D\}$ and $\{B, C, D\}$.

Reduced Markov Networks

- ▶ If we observe some values, $\mathbf{U} = \mathbf{u}$, in the factor value table, we can eliminate the entries which are inconsistent with $\mathbf{U} = \mathbf{u}$.
- ▶ Let $\mathcal{H}$ be a Markov network over $\mathbf{X}$ and $\mathbf{U} = \mathbf{u}$ a context. The reduced Markov network $\mathcal{H}[\mathbf{u}]$ is a Markov network over the nodes $\mathbf{W} = \mathbf{X} - \mathbf{U}$, where we have an edge $X - Y$ if there is an edge $X - Y$ in $\mathcal{H}$.

Reduced Markov Networks

Figure 5: A reduced Markov network example. (a) Original set of factors. (b) Reduced to the context $G = g$. (c) Reduced to the context $G = g, S = s$.

Reduced Markov Networks

- ▶ Conditioning on a context $\mathbf{U}$ in Markov networks eliminates edges from the graph.
- ▶ In a Bayesian network, conditioning on evidence can create new dependencies.

Reduced Markov Networks

- ▶ Markov Random Fields:
 - ▶ Pairwise Markov network.
 - ▶ They are simple.
 - ▶ Interactions on edges are an important special case that often arises in practice.

Markov Network Independencies

- ▶ Let $\mathcal{H}$ be a Markov network and let $X_1 - \dots - X_k$ be a path in $\mathcal{H}$.
- ▶ Let $\mathbf{Z} \subseteq \mathcal{X}$ be a set of observed variables.
- ▶ The path $X_1 - \dots - X_k$ is active given $\mathbf{Z}$ if none of the X_i 's, $i = 1, \dots, k$, is in $\mathbf{Z}$.
- ▶ A set of nodes $\mathbf{Z}$ separates $\mathbf{X}$ and $\mathbf{Y}$ in $\mathcal{H}$, denoted $\text{sep}_{\mathcal{H}}(\mathbf{X}; \mathbf{Y} | \mathbf{Z})$, if there is no active path between any node $X \in \mathbf{X}$ and $Y \in \mathbf{Y}$ given $\mathbf{Z}$.
- ▶ We define the global independencies associated with $\mathcal{H}$ to be

$$\mathcal{I}(\mathcal{H}) = \{(\mathbf{X} \perp \mathbf{Y} | \mathbf{Z}) : \text{sep}_{\mathcal{H}}(\mathbf{X}; \mathbf{Y} | \mathbf{Z})\}.$$

Learning Undirected Models

- ▶ Like in Bayesian networks, once the joint distribution is generated, any kind of question can be answered using conditional probabilities and marginalization.
- ▶ However, a key distinction between Markov networks and Bayesian networks is normalization.
- ▶ Markov networks use a global normalization constant called the partition function.
- ▶ Bayesian networks involve local normalization within each conditional probability distribution.

Learning Undirected Models

- ▶ The global factor couples all of the parameters across the network, preventing us from decomposing the problem and estimating local groups of parameters separately.
- ▶ The global parameter coupling has significant computational ramifications.
- ▶ Even the simple maximum likelihood parameter estimation with complete data cannot be solved in closed form.

Learning Undirected Models

- ▶ We generally have to resort to iterative methods such as gradient ascent.
- ▶ The good news is that the likelihood objective is concave, so the methods are guaranteed to converge to the global optimum.
- ▶ The bad news is that each of the steps in the iterative algorithm requires that we run inference on the network, making even simple parameter estimation a fairly expensive process.
