

# Stream Ciphers

BİL 448/548

Internet Security Protocols

Ali Aydın Selçuk

# Stream Ciphers

- Generate a *pseudo-random* key stream & xor to the plaintext.
- Key: The seed of the PRNG
- Traditional PRNGs (e.g. those used for simulations) are not secure.  
E.g., the linear congruential generator:  
$$X_i = a X_{i-1} + b \pmod{m}$$
for some fixed  $a, b, m$ .
- It passes the randomness tests, but it is predictable if previous output bytes are known.

# Linear Feedback Shift Registers

- Feedback shift register:

(“register”, “feedback”, “shift”)

- LFSR: Feedback fnc. is linear over  $Z_2$  (i.e., an xor):

- Very compact & efficient in hardware (e.g., SIM cards)

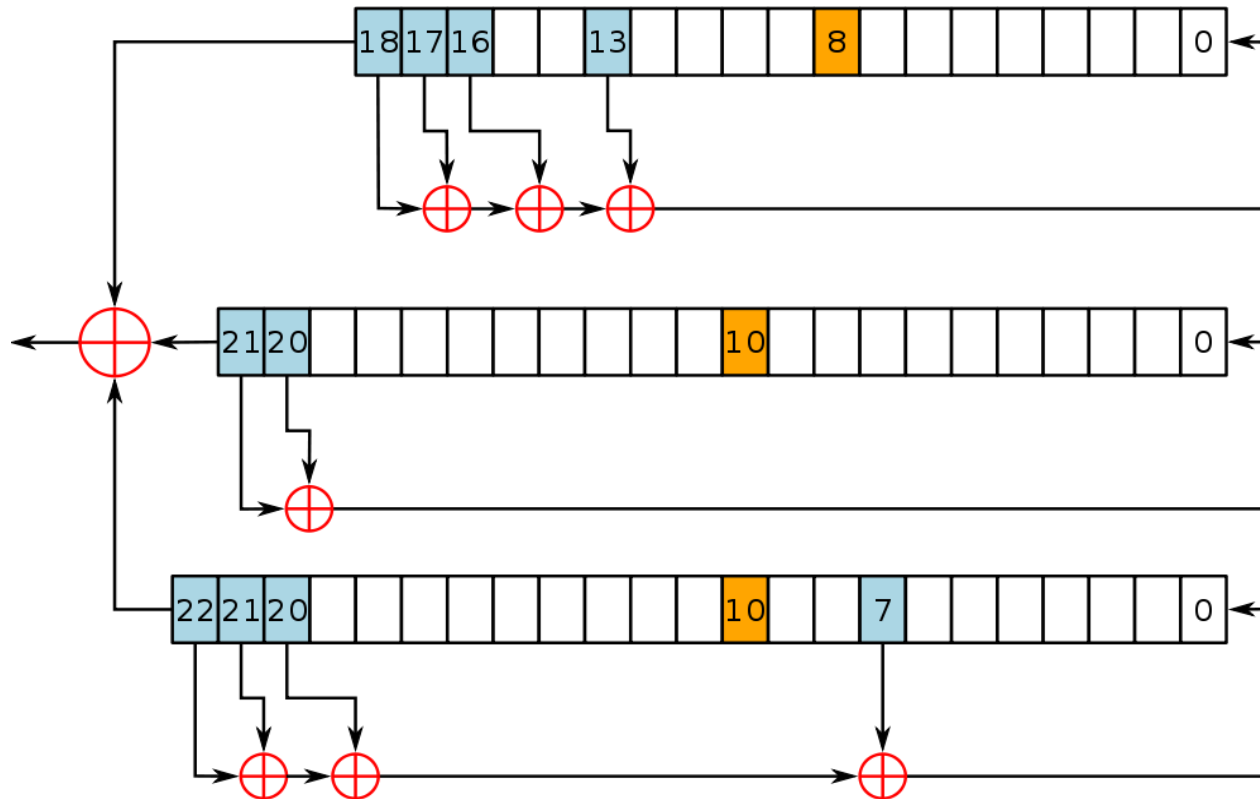

# Stream Ciphers from LFSRs

## Desirable properties of f:

- high non-linearity
- long “cycle period” ( $\sim 2^{n_1+n_2+\dots+n_k}$ )
- low correlation with the input bits

# GSM A5/1

- The A5/1 stream cipher uses three LFSRs.
- A register is clocked if its clocking bit (orange) agrees with one or both of the clocking bits of the other two registers. (majority match)

# Software-Oriented Stream Ciphers

- LFSRs are slow in software
- Alternatives:
  - Block ciphers (or hash functions) in CFB, OFB, CTR modes.
  - Stream ciphers designed for software: RC4, SEAL, SALSA20, SOSEMANUK...

# RC4

(Rivest, 1987)

- Simple, byte-oriented, fast in s/w.
- Popular: Google, MS-Windows, Apple, Oracle Secure SQL, WEP, WPA, etc.

Algorithm:

- Works on  $n$ -bit words. (typically,  $n = 8$ )
- State of the cipher: A permutation of  $\{0, 1, \dots, N-1\}$ , where  $N = 2^n$ , stored at  $S[0, 1, \dots, N-1]$ .
- Key schedule: Expands the  $l$ -byte key (typically 40-256 bits) into the initial state table  $S$ .

# RC4 Key Schedule

The key schedule (i.e., initialization) algorithm:

```
// typically  $n = 8$ ,  $\ell = 16$ 
```

```
for  $i = 1$  to  $2^n - 1$  do:
```

```
     $S[i] \leftarrow i$ 
```

```
 $i \leftarrow 0$ ,  $j \leftarrow 0$ 
```

```
for  $i = 1$  to  $2^n - 1$  do: {
```

```
     $j \leftarrow j + S[i] + K[i \bmod \ell]$ 
```

```
     $S[i] \leftrightarrow S[j]$ 
```

```
}
```

# RC4 Encryption

The encryption (i.e., the PRNG) algorithm:

$i \leftarrow 0, j \leftarrow 0$

loop: {

$i \leftarrow i + 1$

$j \leftarrow j + S[i]$

$S[i] \leftrightarrow S[j]$

output  $S[S[i] + S[j]]$

}

# IV for Stream Ciphers

- Use of an initialization vector is crucial in a stream cipher.
- Otherwise, the same stream will be produced each time the key is used (i.e., for each packet).
- The cipher may specify how to incorporate the IV. e.g., A5/1 mixes 22-bit frame no. into registers.
- Otherwise, ad hoc methods are used. e.g., WEP uses RC4 with 128-bit  $K' = (IV \parallel K)$  for a 24-bit IV and a 104-bit K.

# Speed of Software Stream Ciphers

(Crypto++ 5.6 benchmarks, 2.2 GHz AMD Opteron 8354.  
March 2009.)

Algorithm	Speed (MiByte/s.)
3DES / CTR	17
AES-128 / CBC	148
AES-128 / CTR	198
RC4	124
SEAL	447
SOSEMANUK	767
SALSA20	953
