## CS473-Algorithms I

## Lecture 10 Dynamic Programming <br> View in slide-show mode

## Introduction

- An algorithm design paradigm like divide-and-conquer
- "Programming": A tabular method (not writing computer code)

Older sense of planning or scheduling, typically by filling in a table

- Divide-and-Conquer (DAC): subproblems are independent
- Dynamic Programming (DP): subproblems are not independent
- Overlapping subproblems: subproblems share sub-subproblems
- In solving problems with overlapping subproblems
- A DAC algorithm does redundant work
- Repeatedly solves common subproblems
- A DP algorithm solves each problem just once
- Saves its result in a table

## CS473-Algorithms I

## Problem 1: Fibonacci Numbers

## Example: Fibonacci Numbers (Recursive Solution)

## REC-FIBO(n)

if $\mathrm{n}<2$
return n
else
return $\mathrm{REC}-\mathrm{FIBO}(\mathrm{n}-1)$

+ REC-FIBO(n-2)

Overlapping subproblems in different recursive calls. Repeated work!

## Example: Fibonacci Numbers (Recursive Solution)

## Recurrence:

$$
\begin{aligned}
\mathrm{T}(\mathrm{n})= & \mathrm{T}(\mathrm{n}-1)+\mathrm{T}(\mathrm{n}-2)+1 \\
& \Rightarrow \text { exponential runtime }
\end{aligned}
$$

Recursive algorithm inefficient because it recomputes the same $\mathrm{F}(\mathrm{i})$ repeatedly in different branches of the recursion tree.

## Example: Fibonacci Numbers (Bottom-up Computation)

## Reminder: <br> $\mathrm{F}(0)=0$ and $\mathrm{F}(1)=1$ <br> $\mathrm{F}(\mathrm{n})=\mathrm{F}(\mathrm{n}-1)+\mathrm{F}(\mathrm{n}-2)$

## ITER-FIBO(n)

$\mathrm{F}[0]=0$
$\mathrm{F}[1]=1$
for $\mathrm{i}=2$ to n do
$\mathrm{F}[\mathrm{i}]=\mathrm{F}[\mathrm{i}-1]+\mathrm{F}[\mathrm{i}-2]$
return $\mathrm{F}[\mathrm{n}]$

Runtime: $\Theta$ (n)

## Optimization Problems

- DP typically applied to optimization problems
- In an optimization problem
- There are many possible solutions (feasible solutions)
- Each solution has a value
- Want to find an optimal solution to the problem
- A solution with the optimal value (min or max value)
- Wrong to say "the" optimal solution to the problem
- There may be several solutions with the same optimal value

## Development of a DP Algorithm

1. Characterize the structure of an optimal solution
2. Recursively define the value of an optimal solution
3. Compute the value of an optimal solution in a bottom-up fashion
4. Construct an optimal solution from the information computed in Step 3

## CS473 - Algorithms I

## Problem 2: <br> Matric Chain Multiplication

## Example: Matrix-chain Multiplication

- Input: a sequence (chain) $\left\langle\mathrm{A}_{1}, \mathrm{~A}_{2}, \ldots, \mathrm{~A}_{n}\right\rangle$ of $n$ matrices
- Aim: compute the product $\mathrm{A}_{1} \cdot \mathrm{~A}_{2} \cdot \ldots \cdot \mathrm{~A}_{n}$
- A product of matrices is fully parenthesized if
- It is either a single matrix
- Or, the product of two fully parenthesized matrix products surrounded by a pair of parentheses.

$$
\begin{aligned}
& \left(\mathrm{A}_{i}\left(\mathrm{~A}_{i+1} \mathrm{~A}_{i+2} \ldots . \mathrm{A}_{j}\right)\right) \\
& \left(\left(\mathrm{A}_{i} \mathrm{~A}_{i+1} \mathrm{~A}_{i+2} \ldots . \mathrm{A}_{j-1}\right) \mathrm{A}_{j}\right) \\
& \left(\left(\mathrm{A}_{i} \mathrm{~A}_{i+1} \mathrm{~A}_{i+2} \ldots . \mathrm{A}_{k}\right)\left(\mathrm{A}_{k+1} \mathrm{~A}_{k+2} \ldots \mathrm{~A}_{j}\right)\right) \quad \text { for } i \leq k<j
\end{aligned}
$$

- All parenthesizations yield the same product; matrix product is associative

## Matrix-chain Multiplication: An Example Parenthesization

- Input: $\left\langle\mathrm{A}_{1}, \mathrm{~A}_{2}, \mathrm{~A}_{3}, \mathrm{~A}_{4}\right\rangle$
- 5 distinct ways of full parenthesization
$\left(\mathrm{A}_{1}\left(\mathrm{~A}_{2}\left(\mathrm{~A}_{3} \mathrm{~A}_{4}\right)\right)\right)$
$\left(\mathrm{A}_{1}\left(\left(\mathrm{~A}_{2} \mathrm{~A}_{3}\right) \mathrm{A}_{4}\right)\right)$
$\left(\left(\mathrm{A}_{1} \mathrm{~A}_{2}\right)\left(\mathrm{A}_{3} \mathrm{~A}_{4}\right)\right)$
$\left(\left(\mathrm{A}_{1}\left(\mathrm{~A}_{2} \mathrm{~A}_{3}\right)\right) \mathrm{A}_{4}\right)$
$\left(\left(\left(\mathrm{A}_{1} \mathrm{~A}_{2}\right) \mathrm{A}_{3}\right) \mathrm{A}_{4}\right)$
- The way we parenthesize a chain of matrices can have a dramatic effect on the cost of computing the product

## Reminder: Matrix Multiplication

## MATRIX-MULTIPLY $(A, B)$

if cols[A] $\mathrm{Frows}[\mathrm{B}]$ then
error("incompatible dimensions")
for $i \leftarrow 1$ to rows[A] do
for $j \leftarrow 1$ to cols[B] do
$\mathrm{C}[\mathrm{i}, \mathrm{j}] \leftarrow 0$
for $k \leftarrow 1$ to cols[A] do

$$
\mathrm{C}[i, j] \leftarrow \mathrm{C}[i, j]+\mathrm{A}[\mathrm{i}, \mathrm{k}] \cdot \mathrm{B}[\mathrm{k}, \mathrm{j}]
$$

return C

A B
C

$$
\begin{array}{ll}
\operatorname{rows}(A)=p & \operatorname{rows}(B)=q \\
\operatorname{cols}(A)=q & \operatorname{cols}(B)=r
\end{array}
$$

$$
\operatorname{rows}(\mathrm{C})=\mathrm{p}
$$

$$
\operatorname{cols}(\mathrm{C})=r
$$

## Reminder: Matrix Multiplication

## MATRIX-MULTIPLY $(A, B)$

if cols[A] $\mathrm{Frows}[\mathrm{B}]$ then
error("incompatible dimensions")
for $i \leftarrow 1$ to rows[A] do
for $j \leftarrow 1$ to cols[B] do
$\mathrm{C}[\mathrm{i}, \mathrm{j}] \leftarrow 0$
for $k \leftarrow 1$ to cols[A] do
$\mathrm{C}[\mathrm{i}, \mathrm{j}] \leftarrow \mathrm{C}[i, j]+\mathrm{A}[\mathrm{i}, \mathrm{k}] \cdot \mathrm{B}[\mathrm{k}, \mathrm{j}]$
return C

$$
\begin{array}{ll}
\text { A: } \mathrm{pxq} \mathrm{q} & \mathrm{C}: \mathrm{pxr} \\
\mathrm{~B}: \mathrm{qxr} &
\end{array}
$$

\# of mult-add ops

$$
=\operatorname{rows}[\mathrm{A}] \times \operatorname{cols}[\mathrm{B}] \times \operatorname{cols}[\mathrm{A}]
$$

\# of mult-add ops $=\mathrm{p} \times \mathrm{q} \times \mathrm{r}$

## Matrix Chain Multiplication: Example

$\mathrm{A}_{1}: 10 \mathrm{x} 100$
$\mathrm{A}_{2}: 100 \times 5$
$\mathrm{A}_{3}: 5 \times 50$

Which paranthesization is better? $\left(\mathrm{A}_{1} \mathrm{~A}_{2}\right) \mathrm{A}_{3}$ or $\mathrm{A}_{1}\left(\mathrm{~A}_{2} \mathrm{~A}_{3}\right)$ ?

$$
\begin{aligned}
& \left.\left.\circ\left[{ }^{100}\right] \times A^{5}\right]=\circ{ }^{5} A_{A_{2}}\right] \quad \# \text { of ops: 10.100.5 } \\
& =5000 \\
& \text { \# of ops: } 10 \text {. } 5 \text {. } 50 \\
& =2500 \\
& \text { Total \# of ops: } 7500
\end{aligned}
$$

## Matrix Chain Multiplication: Example

## $\mathrm{A}_{1}: 10 \times 100$ <br> $\mathrm{A}_{2}: 100 \times 5$ <br> $\mathrm{A}_{3}: 5 \times 50$

Which paranthesization is better? $\left(\mathrm{A}_{1} \mathrm{~A}_{2}\right) \mathrm{A}_{3}$ or $\mathrm{A}_{1}\left(\mathrm{~A}_{2} \mathrm{~A}_{3}\right)$ ?

$$
\begin{aligned}
& \varnothing\left[\begin{array}{c}
5 \\
A_{2}
\end{array}\right] \times 5\left[\begin{array}{c}
50 \\
A_{3}
\end{array}\right]=\varnothing\left[\begin{array}{c}
50 \\
\left.A_{2} A_{3}\right]
\end{array}\right. \\
& \text { \# of ops: } 100 \text {. } 5 \text {. } 50 \\
& =25000 \\
& \odot\left[\begin{array}{c}
100 \\
\mathrm{~A}_{1}
\end{array}\right] \times \stackrel{\odot}{\varnothing}\left[\begin{array}{c}
50 \\
\mathrm{~A}_{2} \mathrm{~A}_{3}
\end{array}\right]=\odot\left[\begin{array}{c}
50 \\
\mathrm{~A}_{1} \mathrm{~A}_{2} \mathrm{~A}_{3}
\end{array}\right] \begin{array}{c}
\text { \# of ops: 10. 100 . } 50 \\
=50000 \\
\text { Total \# of ops: 75000 }
\end{array}
\end{aligned}
$$

## Matrix Chain Multiplication: Example

# $\mathrm{A}_{1}: 10 \times 100$ <br> $\mathrm{A}_{2}: 100 \mathrm{x} 5$ <br> $\mathrm{A}_{3}: 5 \times 50$ <br> Which paranthesization is better? $\left(\mathrm{A}_{1} \mathrm{~A}_{2}\right) \mathrm{A}_{3}$ or $\mathrm{A}_{1}\left(\mathrm{~A}_{2} \mathrm{~A}_{3}\right)$ ? 

In summary: $\left(\mathrm{A}_{1} \mathrm{~A}_{2}\right) \mathrm{A}_{3} \rightarrow$ \# of multiply-add ops: 7500 $\mathrm{A}_{1}\left(\mathrm{~A}_{2} \mathrm{~A}_{3}\right) \rightarrow$ \# of multiple-add ops: 75000
$\rightarrow$ First parenthesization yields 10x faster computation

## Matrix-chain Multiplication Problem

Input: A chain $\left\langle\mathrm{A}_{1}, \mathrm{~A}_{2}, \ldots, \mathrm{~A}_{n}\right\rangle$ of $n$ matrices, where $\mathrm{A}_{i}$ is a $p_{i-1} \times p_{i}$ matrix

Objective: Fully parenthesize the product

$$
\mathrm{A}_{1} \cdot \mathrm{~A}_{2} \cdot \ldots \cdot \mathrm{~A}_{n}
$$

such that the number of scalar mult-adds is minimized.

## Counting the Number of Parenthesizations

- Brute force approach: exhaustively check all parenthesizations
- $\mathrm{P}(n)$ : \# of parenthesizations of a sequence of n matrices
- We can split sequence between $k^{\text {th }}$ and $(k+1)^{\text {st }}$ matrices for any $k=1,2, \ldots, n-1$, then parenthesize the two resulting sequences independently, i.e.,

$$
\left(\mathrm{A}_{1} \mathrm{~A}_{2} \mathrm{~A}_{3} \ldots \mathrm{~A}_{k}\right)\left(\mathrm{A}_{k+1} \mathrm{~A}_{k+2} \ldots \mathrm{~A}_{n}\right)
$$

- We obtain the recurrence

$$
\mathrm{P}(1)=1 \text { and } \mathrm{P}(n)=\sum_{k=1}^{n-1} \mathrm{P}(k) \mathrm{P}(n-k)
$$

Number of Parenthesizations: $\sum_{k=1}^{n-1} P(k) P(n-k)$

- The recurrence generates the sequence of Catalan Numbers
- Solution is $\mathrm{P}(n)=\mathrm{C}(n-1)$ where

$$
\mathrm{C}(n)=\frac{1}{n+1}\left[\begin{array}{c}
2 n \\
n
\end{array}\right]=\Omega\left(4^{n} / n^{3 / 2}\right)
$$

- The number of solutions is exponential in $n$
- Therefore, brute force approach is a poor strategy

## The Structure of Optimal Parenthesization

Notation: $\mathrm{A}_{\mathrm{i} . \mathrm{j}}$ : The matrix that results from evaluation of the product: $A_{i} A_{i+1} A_{i+2} \ldots A_{j}$

Observation: Consider the last multiplication operation in any parenthesization: $\left(A_{1} A_{2} \ldots A_{k}\right) .\left(A_{k+1} A_{k+2} \ldots A_{n}\right)$

There is a $k$ value $(1 \leq k<n)$ such that:
First, the product $A_{1 . . k}$ is computed
Then, the product $A_{k+1 . . n}$ is computed
Finally, the matrices $A_{1 . . k}$ and $A_{k+1 . . n}$ are multiplied

## Step 1: Characterize the structure of an optimal solution

$\square$ An optimal parenthesization of product $A_{1} A_{2} \ldots A_{n}$ will be: $\left(A_{1} A_{2} \ldots A_{k}\right) \cdot\left(A_{k+1} A_{k+2} \ldots A_{n}\right)$ for some $k$ value
$\square$ The cost of this optimal parenthesization will be:
Cost of computing $\mathrm{A}_{1 . . \mathrm{k}}$

+ Cost of computing $\mathrm{A}_{\mathrm{k}+1 . . \mathrm{n}}$
+ Cost of multiplying $\mathrm{A}_{1 . \mathrm{k}} \cdot \mathrm{A}_{\mathrm{k}+1 . . \mathrm{n}}$

## Step 1: Characterize the Structure of an Optimal Solution

- Key observation: Given optimal parenthesization
$\left(\mathrm{A}_{1} \mathrm{~A}_{2} \mathrm{~A}_{3} \ldots \mathrm{~A}_{k}\right) \cdot\left(\mathrm{A}_{k+1} \mathrm{~A}_{k+2} \ldots \mathrm{~A}_{n}\right)$
- Parenthesization of the subchain $\mathrm{A}_{1} \mathrm{~A}_{2} \mathrm{~A}_{3} \ldots \mathrm{~A}_{k}$
- Parenthesization of the subchain $\mathrm{A}_{k+1} \mathrm{~A}_{k+2} \ldots \mathrm{~A}_{n}$
should both be optimal

Thus, optimal solution to an instance of the problem contains optimal solutions to subproblem instances
i.e., optimal substructure within an optimal solution exists.

## Step 2: A Recursive Solution

Step 2: Define the value of an optimal solution recursively in terms of optimal solutions to the subproblems

Assume we are trying to determine the min cost of computing $\mathrm{A}_{\mathrm{i} . \mathrm{j}}$
$\mathrm{m}_{\mathrm{i}, \mathrm{j}}$ : min \# of scalar multiply-add opns needed to compute $\mathrm{A}_{\mathrm{i} . \mathrm{j}}$

$$
\text { Note: The optimal cost of the original problem: } m_{1, n}
$$

How to compute $\mathrm{m}_{\mathrm{i}, \mathrm{j}}$ recursively?

## Step 2: A recursive Solution

Base case: $\mathrm{m}_{\mathrm{i}, \mathrm{i}}=0$ (single matrix, no multiplication)
Let the size of matrix $A_{i}$ be $\left(p_{i-1} \times p_{i}\right)$
Consider an optimal parenthesization of chain $\mathrm{A}_{\mathrm{i}} \ldots \mathrm{A}_{\mathrm{j}}$ :

$$
\left(A_{i} \ldots A_{k}\right) \cdot\left(A_{k+1} \ldots A_{j}\right)
$$

The optimal cost:

$$
m_{i, j}=m_{i, k}+m_{k+1, j}+p_{i-1} \times p_{k} \times p_{j}
$$

where: $\quad \mathrm{m}_{\mathrm{i}, \mathrm{k}}$ : Optimal cost of computing $\mathrm{A}_{\mathrm{i}, \mathrm{k}}$

$$
\begin{aligned}
& m_{k+1, j}: \text { Optimal cost of computing } A_{k+1 . j} \\
& p_{i-1} \times p_{k} \times p_{j}: \text { Cost of multiplying } A_{i . . k} \text { and } A_{k+1 \ldots . . j}
\end{aligned}
$$

## Step 2: A Recursive Solution

In an optimal parenthesization:
k must be chosen to minimize $\mathrm{m}_{\mathrm{ij}}$

The recursive formulation for $\mathrm{m}_{\mathrm{ij}}$ :

$$
m_{i j}= \begin{cases}0 & \text { if } i=j \\ {\operatorname{MIN}\left\{m_{i k}+m_{k+1, j}+p_{i-1} p_{k} p_{j}\right\}}^{i \leq k<j} & \text { if } i<j \\ \hline\end{cases}
$$

## Step 2: A Recursive Solution

- The $m_{i j}$ values give the costs of optimal solutions to subproblems
- In order to keep track of how to construct an optimal solution
- Define $s_{i j}$ to be the value of $k$ which yields the optimal split of the subchain $\mathrm{A}_{i . j}$
That is, $s_{i j}=k$ such that

$$
m_{i j}=m_{i k}+m_{k+1, j}+p_{i-1} p_{k} p_{j} \quad \text { holds }
$$

## Direct Recursion: Inefficient!

## Recursive matrix-chain order

## $\mathbf{R M C}(p, i, j)$ <br> if $i=j$ then return 0

$m[i, j] \leftarrow \infty$
for $k \leftarrow i$ to $j-1$ do

$$
q \leftarrow \operatorname{RMC}(p, i, k)+\operatorname{RMC}(p, k+1, j)+p_{i-1} p_{k} p_{j}
$$

if $q<m[i, j]$ then

$$
m[i, j] \leftarrow q
$$

return $m[i, j]$

## Direct Recursion: Inefficient!

Recursion tree for $\operatorname{RMC}(p, 1,4)$
Nodes are labeled with $i$ and $j$ values

## Computing the Optimal Cost (Matrix-Chain Multiplication)

An important observation:

- We have relatively few subproblems
- one problem for each choice of $i$ and $j$ satisfying $1 \leq i \leq j \leq n$
- total $n+(n-1)+\ldots+2+1=\frac{1}{2} n(n+1)=\Theta\left(n^{2}\right)$ subproblems
- We can write a recursive algorithm based on recurrence.
- However, a recursive algorithm may encounter each subproblem many times in different branches of the recursion tree
- This property, overlapping subproblems, is the second important feature for applicability of dynamic programming

## Computing the Optimal Cost (Matrix-Chain Multiplication)

Compute the value of an optimal solution in a bottom-up fashion

- matrix $\mathrm{A}_{i}$ has dimensions $p_{i-1} \times p_{i}$ for $i=1,2, \ldots, n$
- the input is a sequence $\left\langle p_{0}, p_{1}, \ldots, p_{n}\right\rangle$ where length $[p]=n+1$

Procedure uses the following auxiliary tables:
$-m[1 \ldots n, 1 \ldots n]$ : for storing the $m[i, j]$ costs
$-s[1 \ldots n, 1 \ldots n]$ : records which index of $k$ achieved the optimal cost in computing $m[i, j]$

## Bottom-up computation

$$
m_{i j}=\min _{i<k j}\left\{m_{i k}+m_{k+1, j}+p_{i 1} p_{k} p_{j}\right\}
$$

How to choose the order in which we process $\mathrm{m}_{\mathrm{ij}}$ values?

Before computing $\mathrm{m}_{\mathrm{ij}}$, we have to make sure that the values for $m_{i k}$ and $m_{k+1, j}$ have been computed for all $k$.

$$
m_{i j}=\min \left\{m_{i k}+m_{k+1, j}+p_{i 1} p_{k} p_{j}\right\}
$$

```
i k<j
```

$\mathrm{m}_{\mathrm{ij}}$ must be processed after $\mathrm{m}_{\mathrm{ik}}$ and $\mathrm{m}_{\mathrm{j}, \mathrm{k}+1}$

Reminder: $\mathrm{m}_{\mathrm{ij}}$ computed only for $\mathrm{j}>\mathrm{i}$

$$
m_{i j}=\min \left\{m_{i k}+m_{k+1, j}+p_{i 1} p_{k} p_{j}\right\}
$$

```
i k<j
```

$\mathrm{m}_{\mathrm{ij}}$ must be processed after $\mathrm{m}_{\mathrm{ik}}$ and $\mathrm{m}_{\mathrm{j}, \mathrm{k}+1}$

How to set up the iterations over i and j to compute $m_{i j}$ ?

$$
m_{i j}=\min \left\{m_{i k}+m_{k+1, j}+p_{i 1} p_{k} p_{j}\right\}
$$

```
ik<j
```

If the entries $\mathrm{m}_{\mathrm{ij}}$ are computed in the shown order, then $\mathrm{m}_{\mathrm{ik}}$ and $\mathrm{m}_{\mathrm{k}+1, \mathrm{j}}$ values are guaranteed to be computed before $\mathrm{m}_{\mathrm{ij}}$.

## $m_{i j}=\min \left\{m_{i k}+m_{k+1, j}+p_{i} p_{k} p_{j}\right\}$

## $m_{i j}=\min \left\{m_{i k}+m_{k+1, j}+p_{i} p_{k} p_{j}\right\}$

$i_{k<j}$

for $\ell=2$ to n
for $\mathrm{i}=1$ to $\mathrm{n}-\ell+1$
$\mathrm{j}=\mathrm{i}+\ell-1$
$\mathrm{m}_{\mathrm{ij}}=\ldots$

Cevdet Aykanat and Mustafa Ozdal

## Algorithm for Computing the Optimal Costs

## MATRIX-CHAIN-ORDER $(p)$

$n \leftarrow$ length $[p]-1$
for $i \leftarrow 1$ to $n$ do

$$
m[i, i] \leftarrow 0
$$

for $\ell \leftarrow 2$ to $n$ do

$$
\begin{aligned}
& \text { for } i \leftarrow 1 \text { to } n-\ell+1 \text { do } \\
& \qquad \begin{array}{l}
j \leftarrow i+\ell-1 \\
m[i, j] \leftarrow \infty \\
\text { for } k \leftarrow i \text { to } j-1 \text { do } \\
\quad q \leftarrow m[i, k]+m[k+1, j]+p_{i-1} p_{k} p_{j} \\
\quad \text { if } q<m[i, j] \text { then } \\
\\
\quad m[i, j] \leftarrow q \\
\quad s[i, j] \leftarrow k
\end{array}
\end{aligned}
$$

return $m$ and $s$

## Algorithm for Computing the Optimal Costs

- The algorithm first computes
$m[i, i] \leftarrow 0$ for $i=1,2, \ldots, n$ min costs for all chains of length 1
- Then, for $\ell=2,3, \ldots, n$ computes
$m[i, i+\ell-1]$ for $i=1, \ldots, n-\ell+1$ min costs for all chains of length $\ell$
- For each value of $\ell=2,3, \ldots, n$,
$m[i, i+\ell-1]$ depends only on table entries $m[i, k] \& m[k+1, i+\ell-1]$ for $i \leq k<i+\ell-1$, which are already computed

## Algorithm for Computing the Optimal Costs

## Table access pattern in computing $m[i, j] \mathrm{s}$ for $\ell=j-i+1$

$$
\begin{aligned}
& \text { for } k \leftarrow i \text { to } j-1 \text { do } \\
& \qquad \begin{aligned}
& q \leftarrow m[i, k]+m[k+1, j]+p_{i-1} p_{k} p_{j} \\
& \\
& \square \text { Table entries currently computed } \\
& \\
& \text { Table entries already computed } \\
& \text { Table entries referenced }
\end{aligned}
\end{aligned}
$$

## Table access pattern in computing $m[i, j]$ s for $\ell=j-i+1$

## Table access pattern in computing $m[i, j] \mathrm{s}$ for $\ell=j-i+1$

## Table access pattern in computing $m[i, j] \mathrm{s}$ for $\ell=j-i+1$

## Table access pattern in computing $m[i, j]$ s for $\ell=j-i+1$

## Example

$$
m_{i j}=\min _{i k<j}\left\{m_{i k}+m_{k+1, j}+p_{i 1} p_{k} p_{j}\right\}
$$

$\mathrm{A}_{1}:(30 \times 35)$
$A_{2}:(35 \times 15)$
$\mathrm{A}_{3}:(15 \times 5)$
$\mathrm{A}_{4}:(5 \times 10)$
$\mathrm{A}_{5}:(10 \times 20)$
$\mathrm{A}_{6}:(20 \times 25)$
Compute $\mathrm{m}_{25}$

cost $=\mathrm{m}_{22}+\mathrm{m}_{35}+\mathrm{p}_{1} \mathrm{p}_{2} \mathrm{p}_{5}$
$=0+2500+35 \times 15 \times 20$
$=13000$

Choose the $k$ value that leads to min cost

## Example

$$
m_{i j}=\min _{i k<j}\left\{m_{i k}+m_{k+1, j}+p_{i 1} p_{k} p_{j}\right\}
$$

$\mathrm{A}_{1}:(30 \times 35)$
$A_{2}:(35 \times 15)$
$\mathrm{A}_{3}:(15 \times 5)$
$\mathrm{A}_{4}:(5 \times 10)$
$\mathrm{A}_{5}:(10 \times 20)$
$\mathrm{A}_{6}:(20 \times 25)$

Compute $\mathrm{m}_{25}$
$\mathrm{k}=3$
$\left(\mathrm{A}_{2} \mathrm{~A}_{3}\right)\left(\mathrm{A}_{4} \mathrm{~A}_{5}\right)$
cost $=\mathrm{m}_{23}+\mathrm{m}_{45}+\mathrm{p}_{1} \mathrm{p}_{3} \mathrm{p}_{5}$
$=2625+1000+35 \times 5 \times 20$
$=7125$

| 1 | 2 | 3 | 4 | 5 | 6 |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 0 | 15750 | 7875 | 9375 |  |  | 1 |
|  | 0 | 2625 | 4375 | $? ? ?$ |  | 2 |

|  |  |  |  | 0 | 5000 | 5 |
|  |  |  |  |  | 0 | 6 |

Choose the $k$ value that leads to min cost

## Example

$$
m_{i j}=\min _{i k<j}\left\{m_{i k}+m_{k+1, j}+p_{i 1} p_{k} p_{j}\right\}
$$

$\mathrm{A}_{1}:(30 \times 35)$
$A_{2}:(35 \times 15)$
$\mathrm{A}_{3}:(15 \times 5)$
$\mathrm{A}_{4}:(5 \times 10)$
$\mathrm{A}_{5}:(10 \times 20)$
$\mathrm{A}_{6}:(20 \times 25)$
Compute $\mathrm{m}_{25}$

cost $=\mathrm{m}_{24}+\mathrm{m}_{55}+\mathrm{p}_{1} \mathrm{p}_{4} \mathrm{p}_{5}$
$=4375+0+35 \times 10 \times 20$
Choose the $k$ value
that leads to min cost

## Example

$$
m_{i j}=\min _{i k<j}\left\{m_{i k}+m_{k+1, j}+p_{i 1} p_{k} p_{j}\right\}
$$

$\mathrm{A}_{1}$ : (30x35)
$\mathrm{A}_{2}$ : $(35 \times 15)$
$\mathrm{A}_{3}$ : $(15 \times 5)$
$\mathrm{A}_{4}:(5 \times 10)$
$\mathrm{A}_{5}$ : $(10 \times 20)$
$\mathrm{A}_{6}$ : $(20 \times 25)$
Compute $\mathrm{m}_{25}$
$\mathrm{k}=3$
$\left(\mathrm{A}_{2} \mathrm{~A}_{3}\right)\left(\mathrm{A}_{4} \mathrm{~A}_{5}\right)$

$$
\begin{aligned}
\mathrm{m}_{25} & =7125 \\
\mathrm{~s}_{25} & =3
\end{aligned}
$$

| 1 | 2 | 3 | 4 | 5 | 6 |  |

Choose $k=3$

## Constructing an Optimal Solution

- MATRIX-CHAIN-ORDER determines the optimal \# of scalar mults/adds
- needed to compute a matrix-chain product
- it does not directly show how to multiply the matrices
- That is,
- it determines the cost of the optimal solution(s)
- it does not show how to obtain an optimal solution
- Each entry $s[i, j]$ records the value of $k$ such that optimal parenthesization of $\mathrm{A}_{i} \ldots \mathrm{~A}_{j}$ splits the product between $\mathrm{A}_{k} \& \mathrm{~A}_{k+1}$
- We know that the final matrix multiplication in computing $\mathrm{A}_{1 \ldots n}$ optimally is $\mathrm{A}_{1 \ldots s[1, n]} \times \mathrm{A}_{s[1, n]+1, n}$

## Example: Constructing an Optimal Solution

Reminder: $\mathrm{s}_{\mathrm{ij}}$ is the optimal top-level split of $\mathrm{A}_{\mathrm{i}} \ldots \mathrm{A}_{\mathrm{j}}$

What is the optimal top-level split for:

$$
\begin{gathered}
\mathrm{A}_{1} \mathrm{~A}_{2} \mathrm{~A}_{3} \mathrm{~A}_{4} \mathrm{~A}_{5} \mathrm{~A}_{6} \\
\mathrm{~s}_{16}=3
\end{gathered}
$$

## Example: Constructing an Optimal Solution

Reminder: $\mathrm{s}_{\mathrm{ij}}$ is the optimal top-level split of $\mathrm{A}_{\mathrm{i}} \ldots \mathrm{A}_{\mathrm{j}}$

$$
\mathrm{k}=3
$$

$$
\downarrow
$$

$\left(\mathrm{A}_{1} \mathrm{~A}_{2} \mathrm{~A}_{3}\right)\left(\mathrm{A}_{4} \mathrm{~A}_{5} \mathrm{~A}_{6}\right)$

What is the optimal split for $\mathrm{A}_{1} \ldots \mathrm{~A}_{3}$ ? $\mathrm{s}_{13}=1$
What is the optimal split for $\mathrm{A}_{4} \ldots \mathrm{~A}_{6}$ ? $\mathrm{s}_{46}=5$

## Example: Constructing an Optimal Solution

Reminder: $\mathrm{s}_{\mathrm{ij}}$ is the optimal top-level split of $\mathrm{A}_{\mathrm{i}} \ldots \mathrm{A}_{\mathrm{j}}$

What is the optimal split for $A_{1} \ldots A_{3}$ ? $s_{13}=1$
What is the optimal split for $\mathrm{A}_{4} \ldots \mathrm{~A}_{6}$ ? $\mathrm{s}_{46}=5$

## Example: Constructing an Optimal Solution

Reminder: $\mathrm{s}_{\mathrm{ij}}$ is the optimal top-level split of $\mathrm{A}_{\mathrm{i}} \ldots \mathrm{A}_{\mathrm{j}}$

$$
\left(\left(\mathrm{A}_{1}\right)\left(\mathrm{A}_{2} \mathrm{~A}_{3}\right)\right)\left(\left(\mathrm{A}_{4} \mathrm{~A}_{5}\right)\left(\mathrm{A}_{6}\right)\right)
$$

What is the optimal split for $\mathrm{A}_{2} \mathrm{~A}_{3}$ ?

$$
\begin{aligned}
& \mathrm{s}_{23}=2 \\
& \mathrm{~s}_{45}=4
\end{aligned}
$$

What is the optimal split for $\mathrm{A}_{4} \mathrm{~A}_{5}$ ?

## Example: Constructing an Optimal Solution

Reminder: $\mathrm{s}_{\mathrm{ij}}$ is the optimal top-level split of $\mathrm{A}_{\mathrm{i}} \ldots \mathrm{A}_{\mathrm{j}}$

What is the optimal split for $\mathrm{A}_{2} \mathrm{~A}_{3}$ ?

$$
\begin{aligned}
& \mathrm{s}_{23}=2 \\
& \mathrm{~s}_{45}=4
\end{aligned}
$$

What is the optimal split for $\mathrm{A}_{4} \mathrm{~A}_{5}$ ?

## Constructing an Optimal Solution

Earlier optimal matrix multiplications can be computed recursively
Given:

- the chain of matrices $A=\left\langle\mathrm{A}_{1}, \mathrm{~A}_{2}, \ldots \mathrm{~A}_{n}\right\rangle$
- the $s$ table computed by MATRIX-CHAIN-ORDER

The following recursive procedure computes the matrix-chain product $\mathrm{A}_{i \ldots, j}$
MATRIX-CHAIN-MULTIPLY(A, $s, i, j$ )
if $j>i$ then
$\mathrm{X} \leftarrow$ MATRIX-CHAIN-MULTIPLY(A, $s, i, s[i, j])$
$\mathrm{Y} \leftarrow$ MATRIX-CHAIN-MULTIPLY(A, $s, s[i, j]+1, j)$
return MATRIX-MULTIPLY(X, Y)
else
return $\mathrm{A}_{i}$
Invocation: MATRIX-CHAIN-MULTIPLY(A, $s, 1, n$ )

## Example: Recursive Construction of an Optimal Solution

```
MCM(1,6)
    X\leftarrowMCM(1,3)=( A A A A A A ) 
    Y\leftarrowMCM(4,6)=(A A A A S A 
    return (?)
\[
\begin{aligned}
& \rightarrow \operatorname{MCM}(1,3) \\
& \quad \mathrm{X} \leftarrow \mathrm{MCM}(1,1)=\mathrm{A}_{1}-\cdots \cdots \text { return } \mathrm{A}_{1} \\
& \mathrm{Y} \leftarrow \mathrm{MCM}(2,3)=\left(\mathrm{A}_{2} \mathrm{~A}_{3}\right) \\
& \text { return }(?)
\end{aligned}
\]
```

## Example: Recursive Construction of an Optimal Solution

```
MCM(1,6)
X\leftarrowMCM(1,3)=(\mp@subsup{A}{1}{}(\mp@subsup{A}{2}{}\mp@subsup{A}{3}{}))\cdots\cdotsMMCM(1,3)
Y}\leftarrowMCM(4,6)=(\mp@subsup{\textrm{A}}{4}{}\mp@subsup{\textrm{A}}{5}{}\mp@subsup{\textrm{A}}{6}{}
return (?)
X}\leftarrowMCM(1,1)=\mp@subsup{A}{1}{-}~
Y}\leftarrow\textrm{MCM}(2,3)=(\mp@subsup{\textrm{A}}{2}{}\mp@subsup{\textrm{A}}{3}{})->\cdots->\textrm{MCM}(2,3
return (A}\mp@subsup{\textrm{A}}{1}{}(\mp@subsup{\textrm{A}}{2}{}\mp@subsup{\textrm{A}}{3}{}))\quad\textrm{X}\leftarrow\textrm{MCM}(2,2)=\mp@subsup{\textrm{A}}{2}{}\longrightarrow\cdots\mathrm{ return A
Y}\leftarrowMCM(3,3)=\mp@subsup{A}{3}{}\longrightarrow\longrightarrowreturn A A S
return ( (A2 A 3)
```

## Example: Recursive Construction of an Optimal Solution

## Table reference pattern for $m[i, j](1 \leq i \leq j \leq n)$

## Table reference pattern for $m[i, j](1 \leq i \leq j \leq n)$

$R(i, j)=\#$ of times that $m[i, j]$ is referenced in computing other entries

$$
\begin{aligned}
R(i, j) & =(n-j)+(i-1) \\
& =(n-1)-(j-i)
\end{aligned}
$$

The total \# of references for the entire table is

$$
\underbrace{n}_{i=1 j=i} R(i, j)=\frac{n^{3} n}{3}
$$

1. Identification of the optimal substructure property
2. Recursive formulation to compute the cost of the optimal solution
3. Bottom-up computation of the table entries
4. Constructing the optimal solution by backtracing the table entries

## Elements of Dynamic Programming

- When should we look for a DP solution to an optimization problem?
- Two key ingredients for the problem
- Optimal substructure
- Overlapping subproblems

## DP Hallmark \#1

## Optimal Substructure

- A problem exhibits optimal substructure
- if an optimal solution to a problem contains within it optimal solutions to subproblems
- Example: matrix-chain-multiplication

Optimal parenthesization of $\mathrm{A}_{1} \mathrm{~A}_{2} \ldots \mathrm{~A}_{n}$ that splits the product between $\mathrm{A}_{k}$ and $\mathrm{A}_{k+1}$,
contains within it optimal soln's to the problems of parenthesizing $\mathrm{A}_{1} \mathrm{~A}_{2} \ldots \mathrm{~A}_{k}$ and $\mathrm{A}_{k+1} \mathrm{~A}_{k+2} \ldots \mathrm{~A}_{n}$

## Optimal Substructure

## Finding a suitable space of subproblems

- Iterate on subproblem instances
- Example: matrix-chain-multiplication
- Iterate and look at the structure of optimal soln' s to subproblems, sub-subproblems, and so forth
- Discover that all subproblems consists of subchains of $\left\langle\mathrm{A}_{1}, \mathrm{~A}_{2}, \ldots, \mathrm{~A}_{n}\right\rangle$
- Thus, the set of chains of the form

$$
\left\langle\mathrm{A}_{i}, \mathrm{~A}_{i+1}, \ldots, \mathrm{~A}_{j}\right\rangle \text { for } 1 \leq i \leq j \leq n
$$

- Makes a natural and reasonable space of subproblems

## DP Hallmark \#2

Overlapping Subproblems

- Total number of distinct subproblems should be polynomial in the input size
- When a recursive algorithm revisits the same problem over and over again we say that the optimization problem has overlapping subproblems

## Overlapping Subproblems

- DP algorithms typically take advantage of overlapping subproblems
- by solving each problem once
- then storing the solutions in a table
where it can be looked up when needed
- using constant time per lookup

## Overlapping Subproblems

## Recursive matrix-chain order

## $\mathbf{R M C}(p, i, j)$ <br> if $i=j$ then return 0

```
m[i,j]}\leftarrow
for \(k \leftarrow i \boldsymbol{t o} j-1\) do
```

$$
q \leftarrow \operatorname{RMC}(p, i, k)+\operatorname{RMC}(p, k+1, j)+p_{i-1} p_{k} p_{j}
$$

if $q<m[i, j]$ then

$$
m[i, j] \leftarrow q
$$

return $m[i, j]$

## Recursive Matrix-chain Order

Recursion tree for $\operatorname{RMC}(p, 1,4)$

Nodes are labeled with $i$ and $j$ values

## Running Time of RMC

$\mathrm{T}(1) \geq 1$
$\mathrm{T}(n) \geq 1+\sum_{k=1}^{n-1}(\mathrm{~T}(k)+\mathrm{T}(n-k)+1)$ for $n>1$

- For $i=1,2, \ldots, n$ each term $\mathrm{T}(i)$ appears twice
- Once as $\mathrm{T}(k)$, and once as $\mathrm{T}(n-k)$
- Collect $n-11$ ' s in the summation together with the front 1

$$
\mathrm{T}(n) \geq 2 \sum_{i=1}^{n-1} \mathrm{~T}(i)+n
$$

- Prove that $\mathrm{T}(n)=\Omega\left(2^{n}\right)$ using the substitution method

## Running Time of RMC: Prove that $\mathrm{T}(n)=\Omega\left(2^{n}\right)$

- Try to show that $\mathrm{T}(n) \geq 2^{n-1}$ (by substitution) Base case: $\mathrm{T}(1) \geq 1=2^{0}=2^{1-1}$ for $n=1$

IH: $\mathrm{T}(i) \geq 2^{i-1}$ for all $i=1,2, \ldots, n-1$ and $n \geq 2$

$$
\begin{aligned}
\mathrm{T}(n) & \geq 2 \sum_{i=1}^{n} 2^{1} 2^{i-1}+n \\
& =2^{n} \sum_{i=0}^{2} 2^{i}+n=2\left(2^{n-1}-1\right)+n \\
& =2^{n-1}+\left(2^{n-1}-2+n\right)
\end{aligned}
$$

$$
\Rightarrow \mathrm{T}(n) \geq 2^{n-1} \quad \text { Q.E.D. }
$$

## Running Time of RMC: $\mathbf{T}(n) \geq 2^{n-1}$

## Whenever

- a recursion tree for the natural recursive solution to a problem contains the same subproblem repeatedly
- the total number of different subproblems is small it is a good idea to see if DP can be applied

## Memoization

- Offers the efficiency of the usual DP approach while maintaining top-down strategy
- Idea is to memoize the natural, but inefficient, recursive algorithm

## Memoized Recursive Algorithm

- Maintains an entry in a table for the soln to each subproblem
- Each table entry contains a special value to indicate that the entry has yet to be filled in
- When the subproblem is first encountered its solution is computed and then stored in the table
- Each subsequent time that the subproblem encountered the value stored in the table is simply looked up and returned

## Memoized Recursive Matrix-chain Order

## Memoized Recursive Algorithm

- The approach assumes that
- The set of all possible subproblem parameters are known
- The relation between the table positions and subproblems is established
- Another approach is to memoize
- by using hashing with subproblem parameters as key

Memoization-based solutions will NOT BE ACCEPTED in the exams!

## Dynamic Programming vs Memoization Summary

- Matrix-chain multiplication can be solved in $\mathrm{O}\left(n^{3}\right)$ time
- by either a top-down memoized recursive algorithm
- or a bottom-up dynamic programming algorithm
- Both methods exploit the overlapping subproblems property
- There are only $\Theta\left(n^{2}\right)$ different subproblems in total
- Both methods compute the soln to each problem once
- Without memoization the natural recursive algorithm runs in exponential time since subproblems are solved repeatedly

## Dynamic Programming vs Memoization Summary

## In general practice

- If all subproblems must be solved at once
- a bottom-up DP algorithm always outperforms a top-down memoized algorithm by a constant factor
because, bottom-up DP algorithm
- Has no overhead for recursion
- Less overhead for maintaining the table
- DP: Regular pattern of table accesses can be exploited to reduce the time and/or space requirements even further
- Memoized: If some problems need not be solved at all, it has the advantage of avoiding solutions to those subproblems

## CS473-Algorithms I

## Problem 3: <br> Longest Common Subsequence

## Definitions

$\square$ A subsequence of a given sequence is just the given sequence with some elements (possibly none) left out
$\square$ Example:

$$
\begin{aligned}
\mathrm{X} & =\langle\mathrm{A}, \mathbf{B}, \mathbf{C}, \mathrm{~B}, \mathrm{D}, \mathrm{~A}, \mathbf{B}\rangle \\
\mathrm{Z} & =\langle\mathbf{B}, \mathbf{C}, \mathrm{D}, \mathbf{B}\rangle \\
& \quad \rightarrow \mathrm{Z} \text { is a subsequence of } \mathrm{X}
\end{aligned}
$$

## Definitions

Formal definition: Given a sequence $X=\left\langle x_{1}, x_{2}, \ldots, x_{m}\right\rangle$,
sequence $Z=\left\langle z_{1}, z_{2}, \ldots, z_{k}\right\rangle$ is a subsequence of $X$
if $\exists$ a strictly increasing sequence $\left\langle i_{1}, i_{2}, \ldots, i_{k}\right\rangle$ of indices of $X$ such that $x_{i}=z_{j}$ for all $j=1,2, \ldots, k$, where $1 \leq k \leq m$ j

Example: $Z=\langle\mathbf{B}, \mathbf{C}, \mathbf{D}, \mathbf{B}\rangle$ is a subsequence of $X=\left\langle\stackrel{1}{1} \stackrel{2}{\mathbf{A}}, \mathbf{B}, \stackrel{3}{\mathbf{C}}, \stackrel{4}{\mathrm{~B}}, \mathbf{5},{ }^{6}, \mathrm{~A},{ }^{7}, \mathbf{B}\right\rangle$ with the index sequence $\left\langle i_{1}, i_{2}, i_{3}, i_{4}\right\rangle=\langle 2,3,5,7\rangle$

## Definitions

If Z is a subsequence of both X and Y , we denote Z as a common subsequence of X and Y .

Example: $\mathrm{X}=\langle\mathrm{A}, \mathrm{B}, \mathrm{C}, \mathrm{B}, \mathrm{D}, \mathbf{A}, \mathrm{B}>$ and $\mathrm{Y}=\langle\mathrm{B}, \mathrm{D}, \mathrm{C}, \mathrm{A}, \mathrm{B}, \mathrm{A}\rangle$
$\mathrm{Z} 1=\langle\mathbf{B}, \mathbf{C}, \mathbf{A}\rangle$ is a common subsequence (of length 3 ) of X and Y .

Two longest common subsequence (LCSs) of X and Y ?

$$
\begin{aligned}
& \mathrm{Z}_{2}=\langle\mathrm{B}, \mathrm{C}, \mathrm{~B}, \mathrm{~A}\rangle \text { of length } 4 \\
& \mathrm{Z} 3=\langle\mathrm{B}, \mathrm{D}, \mathrm{~A}, \mathrm{~B}\rangle \text { of length } 4
\end{aligned}
$$

The optimal solution value $=4$

## Longest Common Subsequence (LCS) Problem

$\square$ LCS problem: Given two sequences $X=\left\langle x_{1}, x_{2}, \ldots, x_{m}\right\rangle$ and $\mathrm{Y}=\left\langle\mathrm{y}_{1}, \mathrm{y}_{2}, \ldots, \mathrm{y}_{\mathrm{n}}\right\rangle$, find the LCS of $\mathrm{X} \& \mathrm{Y}$
$\square$ Brute force approach:

- Enumerate all subsequences of X
- Check if each subsequence is also a subsequence of Y
- Keep track of the LCS
- What is the complexity?

■ There are $2^{\mathrm{m}}$ subsequences of X
$\rightarrow$ Exponential runtime

## Notation

Notation: Let $\mathrm{X}_{\mathrm{i}}$ denote the $\mathrm{i}^{\text {th }}$ prefix of X

$$
\text { i.e. } X_{i}=\left\langle x_{1}, x_{2}, \ldots, x_{i}\right\rangle
$$

Example: $\mathrm{X}=\langle\mathrm{A}, \mathrm{B}, \mathrm{C}, \mathrm{B}, \mathrm{D}, \mathrm{A}, \mathrm{B}\rangle$

$$
\mathrm{X}_{4}=\langle\mathrm{A}, \mathrm{~B}, \mathrm{C}, \mathrm{~B}\rangle, \quad \mathrm{X}_{0}=<>
$$

## Optimal Substructure of an LCS

Let $\mathrm{X}=\left\langle\mathrm{x}_{1}, \mathrm{x}_{2}, \ldots, \mathrm{x}_{\mathrm{m}}\right\rangle$ and $\mathrm{Y}=\left\langle\mathrm{y}_{1}, \mathrm{y}_{2}, \ldots, \mathrm{y}_{\mathrm{n}}\right\rangle$ are given
Let $Z=\left\langle z_{1}, z_{2}, \ldots, z_{k}\right\rangle$ be an LCS of $X$ and $Y$

Question 1: If $\mathrm{x}_{\mathrm{m}}=\mathrm{y}_{\mathrm{n}}$, how to define the optimal substructure?

We must have $\mathrm{z}_{\mathrm{k}}=\mathrm{x}_{\mathrm{m}}=\mathrm{y}_{\mathrm{n}}$ and $\mathrm{Z}_{\mathrm{k}-1}=\operatorname{LCS}\left(\mathrm{X}_{\mathrm{m}-1}, \mathrm{Y}_{\mathrm{n}-1}\right)$

## Optimal Substructure of an LCS

Let $\mathrm{X}=\left\langle\mathrm{x}_{1}, \mathrm{x}_{2}, \ldots, \mathrm{x}_{\mathrm{m}}\right\rangle$ and $\mathrm{Y}=\left\langle\mathrm{y}_{1}, \mathrm{y}_{2}, \ldots, \mathrm{y}_{\mathrm{n}}\right\rangle$ are given
Let $\mathrm{Z}=\left\langle\mathrm{z}_{1}, \mathrm{z}_{2}, \ldots, \mathrm{z}_{\mathrm{k}}\right\rangle$ be an LCS of X and Y

Question 2: If $\mathrm{x}_{\mathrm{m}} \neq \mathrm{y}_{\mathrm{n}}$ and $\mathrm{z}_{\mathrm{k}} \neq \mathrm{x}_{\mathrm{m}}$, how to define the optimal substructure?

We must have $\mathrm{Z}=\operatorname{LCS}\left(\mathrm{X}_{\mathrm{m}-1}, \mathrm{Y}\right)$

## Optimal Substructure of an LCS

Let $\mathrm{X}=\left\langle\mathrm{x}_{1}, \mathrm{x}_{2}, \ldots, \mathrm{x}_{\mathrm{m}}\right\rangle$ and $\mathrm{Y}=\left\langle\mathrm{y}_{1}, \mathrm{y}_{2}, \ldots, \mathrm{y}_{\mathrm{n}}\right\rangle$ are given
Let $\mathrm{Z}=\left\langle\mathrm{z}_{1}, \mathrm{z}_{2}, \ldots, \mathrm{z}_{\mathrm{k}}\right\rangle$ be an LCS of X and Y

Question 3: If $\mathrm{x}_{\mathrm{m}} \neq \mathrm{y}_{\mathrm{n}}$ and $\mathrm{z}_{\mathrm{k}} \neq \mathrm{y}_{\mathrm{n}}$, how to define the optimal substructure?

We must have $\mathrm{Z}=\operatorname{LCS}\left(\mathrm{X}, \mathrm{Y}_{\mathrm{n}-1}\right)$

## Theorem: Optimal Substructure of an LCS

Let $\mathrm{X}=\left\langle\mathrm{x}_{1}, \mathrm{x}_{2}, \ldots, \mathrm{x}_{\mathrm{m}}\right\rangle$ and $\mathrm{Y}=\left\langle\mathrm{y}_{1}, \mathrm{y}_{2}, \ldots, \mathrm{y}_{\mathrm{n}}\right\rangle$ are given
Let $\mathrm{Z}=\left\langle\mathrm{z}_{1}, \mathrm{z}_{2}, \ldots, \mathrm{z}_{\mathrm{k}}\right\rangle$ be an LCS of X and Y

Theorem: Optimal substructure of an LCS:

1. If $x_{m}=y_{n}$
then $\mathrm{z}_{\mathrm{k}}=\mathrm{x}_{\mathrm{m}}=\mathrm{y}_{\mathrm{n}}$ and $\mathrm{Z}_{\mathrm{k}-1}$ is an LCS of $\mathrm{X}_{\mathrm{m}-1}$ and $\mathrm{Y}_{\mathrm{n}-1}$
2. If $\mathrm{x}_{\mathrm{m}} \neq \mathrm{y}_{\mathrm{n}}$ and $\mathrm{z}_{\mathrm{k}} \neq \mathrm{x}_{\mathrm{m}}$
then Z is an LCS of $\mathrm{X}_{\mathrm{m}-1}$ and Y
3. If $\mathrm{x}_{\mathrm{m}} \neq \mathrm{y}_{\mathrm{n}}$ and $\mathrm{z}_{\mathrm{k}} \neq \mathrm{y}_{\mathrm{n}}$
then Z is an LCS of X and $\mathrm{Y}_{\mathrm{n}-1}$

## Optimal Substructure Theorem (case 1)

If $x_{m}=y_{n}$ then $z_{k}=x_{m}=y_{n}$ and $Z_{k-1}$ is an LCS of $X_{m-1}$ and $Y_{n-1}$

## Optimal Substructure Theorem (case 2)

If $x_{m} \neq y_{n}$ and $z_{k} \neq x_{m}$ then $Z$ is an LCS of $X_{m-1}$ and $Y$

## Optimal Substructure Theorem (case 3)

If $x_{m} \neq y_{n}$ and $z_{k} \neq y_{n}$ then $Z$ is an LCS of $X$ and $Y_{n-1}$

## Proof of Optimal Substructure Theorem (case 1)

$$
\text { If } x_{m}=y_{n} \text { then } z_{k}=x_{m}=y_{n} \text { and } Z_{k-1} \text { is an LCS of } X_{m-1} \text { and } Y_{n-1}
$$

Proof: If $z_{k} \neq x_{m}=y_{n}$ then
we can append $x_{m}=y_{n}$ to $Z$ to obtain a common subsequence of length $k+1 \Rightarrow$ contradiction
Thus, we must have $z_{k}=x_{m}=y_{n}$
Hence, the prefix $Z_{k-1}$ is a length-( $k-1$ ) CS of $X_{m-1}$ and $Y_{n-1}$
We have to show that $Z_{k-1}$ is in fact an LCS of $X_{m-1}$ and $Y_{n-1}$
Proof by contradiction:
Assume that $\exists$ a CS $W$ of $X_{m-1}$ and $Y_{n-1}$ with $|W|=k$
Then appending $x_{m}=y_{n}$ to $W$ produces a CS of length $k+1$

## Proof of Optimal Substructure Theorem (case 2)

## If $x_{m} \neq y_{n}$ and $z_{k} \neq x_{m}$ then $Z$ is an LCS of $X_{m-1}$ and $Y$

Proof: If $z_{k} \neq x_{m}$ then $Z$ is a CS of $X_{m-1}$ and $Y_{n}$
We have to show that $Z$ is in fact an LCS of $X_{m-1}$ and $Y_{n}$
(Proof by contradiction)
Assume that $\exists$ a CS $W$ of $X_{m-1}$ and $Y_{n}$ with $|W|>k$
Then $W$ would also be a CS of $X$ and $Y$
Contradiction to the assumption that
$Z$ is an LCS of $X$ and $Y$ with $|Z|=k$

Case 3: Dual of the proof for (case 2)

## A Recursive Solution to Subproblems

Theorem implies that there are one or two subproblems to examine if $x_{m}=y_{n}$ then
we must solve the subproblem of finding an LCS of $X_{m-1} \& Y_{n-1}$ appending $x_{m}=y_{n}$ to this LCS yields an LCS of $X \& Y$ else
we must solve two subproblems

- finding an LCS of $X_{m-1} \& Y$
- finding an LCS of $X \& Y_{n-1}$
longer of these two LCSs is an LCS of $X \& Y$
endif

## Recursive Algorithm (Inefficient!!!)

$\operatorname{LCS}(X, Y)$
$m \leftarrow$ length $[X]$
$n \leftarrow$ length $[Y]$
if $x_{m}=y_{n}$ then
$Z \leftarrow \operatorname{LCS}\left(X_{m-1}, Y_{n-1}\right) \quad D$ solve one subproblem return $\left\langle Z, x_{m}=y_{n}\right\rangle \quad \triangleright$ append $x_{m}=y_{n}$ to $Z$
else

$$
\left.\begin{array}{l}
Z^{\prime} \leftarrow \operatorname{LCS}\left(X_{m-1}, Y\right) \\
Z^{\prime \prime} \leftarrow \operatorname{LCS}\left(X, Y_{n-1}\right)
\end{array}\right\} \triangleright \text { solve two subproblems }
$$ return longer of $Z^{\prime}$ and $Z^{\prime \prime}$

## A Recursive Solution

$c[i, j]$ : length of an LCS of $X_{i}$ and $Y_{j}$

$$
c[i, j]= \begin{cases}0 & \text { if } i=0 \text { or } j=0 \\ c[i-1, j-1]+1 & \text { if } i, j>0 \text { and } x_{i}=y_{j} \\ \max \{c[i, j-1], c[i-1, j]\} & \text { if } i, j>0 \text { and } x_{i} \neq y_{j}\end{cases}
$$

## Computing the Length of an LCS

$\square$ We can easily write an exponential-time recursive algorithm based on the given recurrence. $\rightarrow$ Inefficient!
$\square$ How many distinct subproblems to solve?

$$
\Theta(m n)
$$

$\square$ Overlapping subproblems property: Many subproblems share the same sub-subproblems.
e.g. Finding an LCS to $X_{m-1} \& Y$ and an LCS to $X \& Y_{n-1}$ has the sub-subproblem of finding an LCS to $X_{m-1} \& Y_{n-1}$
$\square$ Therefore, we can use dynamic programming.

## Data Structures

Let:
$c[i, j]$ : length of an LCS of $X_{i}$ and $Y_{j}$
$\mathrm{b}[\mathrm{i}, \mathrm{j}]$ : direction towards the table entry corresponding to the optimal subproblem solution chosen when computing $c[i, j]$. Used to simplify the construction of an optimal solution at the end.

Maintain the following tables:

$$
\begin{aligned}
& \mathrm{c}[0 \ldots \mathrm{~m}, 0 \ldots \mathrm{n}] \\
& \mathrm{b}[1 \ldots \mathrm{~m}, 1 \ldots \mathrm{n}]
\end{aligned}
$$

## Bottom-up Computation

## Reminder:

$$
c[i, j]= \begin{cases}0 & \text { if } i=0 \text { or } j=0 \\ c[i-1, j-1]+1 & \text { if } i, j>0 \text { and } x_{i}=y_{j} \\ \max \{c[i, j-1], c[i-1, j]\} & \text { if } i, j>0 \text { and } x_{i} \neq y_{j}\end{cases}
$$

How to choose the order in which we process $c[i, j]$ values?
The values for $\mathrm{c}[\mathrm{i}-1, \mathrm{j}-1], \mathrm{c}[\mathrm{i}, \mathrm{j}-1]$, and $\mathrm{c}[\mathrm{i}-1, \mathrm{j}]$ must be computed before computing $\mathrm{c}[\mathrm{i}, \mathrm{j}]$.

$$
c[i, j]= \begin{cases}0 & \text { if } i=0 \text { or } j=0 \\ c[i-1, j-1]+1 & \text { if } i, j>0 \text { and } x_{i}=y_{j} \\ \max \{c[i, j-1], c[i-1, j]\} & \text { if } i, j>0 \text { and } x_{i} \neq y_{j}\end{cases}
$$

Need to process: $\mathrm{c}[\mathrm{i}, \mathrm{j}]$
after computing: $\mathrm{c}[\mathrm{i}-1, \mathrm{j}-1]$, $\mathrm{c}[\mathrm{i}, \mathrm{j}-1]$, $c[i-1, j]$

$$

## Computing the Length of an LCS

Operation of LCS－LENGTH on the sequences

$$
\begin{aligned}
& X=\left\langle\begin{array}{llllll}
1 & 2 & 3 & 4 & 5 & 6 \\
\hline
\end{array}, \stackrel{7}{\mathrm{C}}, \mathrm{~B}, \mathrm{D}, \mathrm{~A}, \mathrm{~B}\right\rangle \\
& Y=\langle\mathrm{B}, \underset{1}{\mathrm{D}}, \underset{3}{\mathrm{C}}, \underset{4}{\mathrm{~A}}, \underset{5}{\mathrm{~B}}, \underset{6}{\mathrm{~A}}\rangle
\end{aligned}
$$

Running－time $=\mathrm{O}(m n)$ since each table entry takes $\mathrm{O}(1)$ time to compute LCS of $X \& Y=\langle\mathrm{B}, \mathrm{C}, \mathrm{B}, \mathrm{A}\rangle$

| ${ }^{j}$ | 0 $y_{j}$ | 1 | 2 | 3 <br> C | 4 <br> A | 5 B | 6 <br> A |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

## Constructing an LCS

The $b$ table returned by LCS-LENGTH can be used to quickly construct an LCS of $X \& Y$

Begin at $b[m, n]$ and trace through the table following arrows

Whenever you encounter a " $\ltimes$ " in entry $b[i, j]$
it implies that $x_{i}=y_{j}$ is an element of LCS

The elements of LCS are encountered in reverse order

## Constructing an LCS

PRINT-LCS $(b, X, i, j)$
if $i=0$ or $j=0$ then return

## The initial invocation:

PRINT-LCS $(b, X$, length $[X]$, length $[Y])$
if $b[i, j]=$ " $\kappa$ " then
PRINT-LCS $(b, X, i-1, j-1)$
print $x_{i}$
else if $b[i, j]=$ " $\uparrow$ " then
PRINT-LCS $(b, X, i-1, j)$
else

## PRINT-LCS $(b, X, i, j-1)$

The recursive procedure PRINT-LCS prints out LCS in proper order
This procedure takes $\mathrm{O}(m+n)$ time since at least one of $i$ and $j$ is decremented in each stage of the recursion

## Do we really need the b table (back-pointers)?

|  | $\emptyset$ | B | D | C | A | B | A |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\varnothing$ | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| A | 0 | 0 | 0 | 0 | 1 | 1 | 1 |
| B | 0 | 1 | 1 | 1 | 1 | 2 | 2 |
| C | 0 | 1 | 1 | 2 | 2 | 2 | 2 |
| B | 0 | 1 | 1 | 2 | 2 | 3 | 3 |
| D | 0 | 1 | 2 | 2 | 2 | 3 | 3 |
| A | 0 | 1 | 2 | 2 | 3 | 3 | 4 |
| B | 0 | 1 | 2 | 3 | 3 | 4 | 4 |

## Question: From which neighbor did we expand to the highlighted cell?

Answer: Upper-left neighbor, because $\mathrm{X}[\mathrm{i}]=\mathrm{Y}[\mathrm{j}]$.

## Do we really need the b table (back-pointers)?

|  | $\emptyset$ | B | D | C | A | B | A |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\varnothing$ | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| A | 0 | 0 | 0 | 0 | 1 | 1 | 1 |
| B | 0 | 1 | 1 | 1 | 1 | 2 | 2 |
| C | 0 | 1 | 1 | 2 | 2 | 2 | 2 |
| B | 0 | 1 | 1 | 2 | 2 | 3 | 3 |
| D | 0 | 1 | 2 | 2 | 2 | 3 | 3 |
| A | 0 | 1 | 2 | 2 | 3 | 3 | 4 |
| B | 0 | 1 | 2 | 3 | 3 | 4 | 4 |

## Question: From which neighbor did we expand to the highlighted cell?

Answer: Left neighbor, because $\mathrm{X}[\mathrm{i}] \neq \mathrm{Y}[\mathrm{j}]$ and $\operatorname{LCS}[\mathrm{i}, \mathrm{j}-1]>\operatorname{LCS}[\mathrm{i}-1, \mathrm{j}]$.

## Do we really need the b table (back-pointers)?

|  | $\emptyset$ | B | D | C | A | B | A |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\emptyset$ | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| A | 0 | 0 | 0 | 0 | 1 | 1 | 1 |
| B | 0 | 1 | 1 | 1 | 1 | 2 | 2 |
| C | 0 | 1 | 1 | 2 | 2 | 2 | 2 |
| B | 0 | 1 | 1 | 2 | 2 | 3 | 3 |
| D | 0 | 1 | 2 | 2 | 2 | 3 | 3 |
| A | 0 | 1 | 2 | 2 | 3 | 3 | 4 |
| B | 0 | 1 | 2 | 3 | 3 | 4 | 4 |

## Question: From which neighbor did we expand to the highlighted cell?

Answer: Upper neighbor, because $\mathrm{X}[\mathrm{i}] \neq \mathrm{Y}[\mathrm{j}]$ and $\operatorname{LCS}[\mathrm{i}, \mathrm{j}-1]=\operatorname{LCS}[\mathrm{i}-1, \mathrm{j}]$.
(See pseudo-code to see how ties are handled.)

## Improving the Space Requirements

We can eliminate the $b$ table altogether

- each $c[i, j]$ entry depends only on 3 other c table entries: $c[i-1, j-1], c[i-1, j]$ and $c[i, j-1]$

Given the value of $c[i, j]$ :

- We can determine in $\mathrm{O}(1)$ time which of these 3 values was used to compute $c[i, j]$ without inspecting table $b$
- We save $\Theta(m n)$ space by this method
- However, space requirement is still $\Theta(m n)$ since we need $\Theta(m n)$ space for the $c$ table anyway

## What if we store the last 2 rows only?

To compute $c[i, j]$, we only need $c[i-1, j-1], c[i-1, j]$, and $c[i-1, j-1]$

So, we can store only the last two rows.

## What if we store the last 2 rows only?

To compute $c[i, j]$, we only need $c[i-1, j-1], c[i-1, j]$, and $c[i-1, j-1]$

So, we can store only the last two rows.

## What if we store the last 2 rows only?

To compute $c[i, j]$, we only need $c[i-1, j-1], c[i-1, j]$, and $c[i-1, j-1]$

So, we can store only the last two rows.

This reduces space complexity from $\Theta(\mathrm{mn})$ to $\Theta(\mathrm{n})$.

Is there a problem with this approach?

## What if we store the last 2 rows only?

Is there a problem with this approach?

We cannot construct the optimal solution because we cannot backtrace anymore.

This approach works if we only need the length of an LCS, not the actual LCS.

## CS473-Algorithms I

## Problem 4 <br> Optimal Binary Search Tree

## Reminder: Binary Search Tree (BST)

All keys in the left subtree less than 8

This property holds for all nodes.

All keys in the right subtree greater than 8

Image from Wikimedia

## Binary Search Tree Example

## Example: English-to-French translation

Organize (English, French) word pairs in a BST
> Keyword: English word
> Satellite data: French word

We can search for an
English word (node key) efficiently, and return the corresponding French word (satellite data).

## Binary Search Tree Example

Suppose we know the frequency of each keyword in texts: | $5 \%$ | $\frac{\text { begin }}{50}$ | $\frac{\text { else }}{8 \%}$ | $\frac{\text { end }}{4 \%}$ | $\frac{\text { if }}{10 \%}$ | $\frac{\text { then }}{10 \%}$ | $\frac{\text { while }}{23 \%}$ |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- |

## Cost of a Binary Search Tree

## Cost of a Binary Search Tree

A different binary search tree (BST) leads to a different total cost:

$$
\begin{aligned}
\text { Total cost }= & 1 \times 0.4+2 \times 0.05+2 \times 0.23+ \\
& 3 \times 0.1+4 \times 0.08+4 \times 0.1+ \\
& 5 \times 0.04 \\
= & 2.18
\end{aligned}
$$

This is in fact an optimal BST.

## Optimal Binary Search Tree Problem

## Given:

A collection of $n$ keys $K_{1}<K_{2}<\ldots K_{n}$ to be stored in a BST.
The corresponding $\mathrm{p}_{\mathrm{i}}$ values for $1 \leq \mathrm{i} \leq \mathrm{n}$

$$
\mathrm{p}_{\mathrm{i}} \text { : probability of searching for key } \mathrm{K}_{\mathrm{i}}
$$

Find:
An optimal BST with minimum total cost:

$$
\text { Total cost }={ }_{i}(\text { depth }(i)+1) \times f r e q(i)
$$

Note: The BST will be static. Only search operations will be performed. No insert, no delete, etc.

## Cost of a Binary Search Tree

Lemma 1: Let $\mathrm{T}_{\mathrm{ij}}$ be a BST containing keys $\mathrm{K}_{\mathrm{i}}<\mathrm{K}_{\mathrm{i}+1}<\ldots<\mathrm{K}_{\mathrm{j}}$. Let $\mathrm{T}_{\mathrm{L}}$ and $\mathrm{T}_{\mathrm{R}}$ be the left and right subtrees of T . Then we have:

$$
\operatorname{cost}\left(T_{i j}\right)=\operatorname{cost}\left(T_{L}\right)+\operatorname{cost}\left(T_{R}\right)+p_{h=i} p_{h}
$$

Intuition: When we add the root node, the depth of each node in $T_{L}$ and $T_{R}$ increases by 1 . So, the cost of node h increases by $\mathrm{p}_{\mathrm{h}}$. In addition, the cost of root node r is $\mathrm{p}_{\mathrm{r}}$. That's why, we have the last term at the end of the formula above.

## Optimal Substructure Property

## Lemma 2: Optimal substructure property

Consider an optimal BST $\mathrm{T}_{\mathrm{ij}}$ for keys $\mathrm{K}_{\mathrm{i}}<\mathrm{K}_{\mathrm{i}+1}<\ldots<\mathrm{K}_{\mathrm{j}}$
Let $K_{m}$ be the key at the root of $T_{i j}$
Then:

$\mathrm{T}_{\mathrm{i}, \mathrm{m}-1}$ is an optimal BST for subproblem containing keys: $\mathrm{K}_{\mathrm{i}}<\ldots<\mathrm{K}_{\mathrm{m}-1}$
$\mathrm{T}_{\mathrm{m}+1, \mathrm{j}}$ is an optimal BST for subproblem containing keys: $\mathrm{K}_{\mathrm{m}+1}<\ldots<\mathrm{K}_{\mathrm{j}}$

$$
\operatorname{cost}\left(T_{i j}\right)=\operatorname{cost}\left(T_{i, m 1}\right)+\operatorname{cost}\left(T_{m+1, j}\right)+p_{h=i} p_{h}
$$

## Recursive Formulation

Note: We don't know which root vertex leads to the minimum total cost. So, we need to try each vertex $m$, and choose the one with minimum total cost.
$c[i, j]$ : cost of an optimal BST $T_{i j}$ for the subproblem $K_{i}<\ldots<K_{j}$

$$
c[i, j]=\begin{aligned}
& 0 \\
& \min _{i r}\left\{c\left[\begin{array}{ll}
i, r & 1
\end{array}\right]+c[r-\right. \\
& \\
& \text { where } \quad P_{i j}=p_{h=i}^{j} p_{h}
\end{aligned}
$$

$$
\text { if } \mathrm{i}>\mathrm{j}
$$

## Bottom-up computation

$$
c[i, j]=\begin{array}{ll}
0 & \text { if } \mathrm{i}>\mathrm{j} \\
\min _{i r}\left\{\begin{array}{ll}
\text { i }, r & 1]+c[r+1, j]+P_{i j}
\end{array}\right\} & \text { otherwise }
\end{array}
$$

How to choose the order in which we process $c[i, j]$ values?
Before computing $c[i, j]$, we have to make sure that the values for $\mathrm{c}[\mathrm{i}, \mathrm{r}-1]$ and $\mathrm{c}[\mathrm{r}+1, \mathrm{j}]$ have been computed for all r .

$$
c[i, j]=\begin{array}{ll}
0 & \text { if } \mathbf{i}>\mathrm{j} \\
\min _{i}\left\{c\left[\begin{array}{ll}
i, r & 1
\end{array}\right]+c[r+1, j]+P_{i j}\right\} & \text { otherwise }
\end{array}
$$

$\mathrm{c}[\mathrm{i}, \mathrm{j}]$ must be processed after $c[i, r-1]$ and $c[r+1, j]$

$$
c[i, j]=\begin{array}{ll}
0 & \text { if } \mathrm{i}>\mathrm{j} \\
\min _{i}\left\{c \left[\begin{array}{ll}
i, r & \left.1]+c[r+1, j]+P_{i j}\right\}
\end{array}\right.\right. & \text { otherwise }
\end{array}
$$

> If the entries $c[i, j]$ are computed in the shown order, then $\mathrm{c}[\mathrm{i}, \mathrm{r}-1]$ and $\mathrm{c}[\mathrm{r}+1, \mathrm{j}]$ values are guaranteed to be computed before $\mathrm{c}[\mathrm{i}, \mathrm{j}]$.

## Computing the Optimal BST Cost

## OPTIMAL-BST-COST (p, n)

```
for \(\mathrm{i} \leftarrow 1\) to n do
    \(\mathrm{c}[\mathrm{i}, \mathrm{i}-1] \leftarrow 0\)
    \(\mathrm{c}[\mathrm{i}, \mathrm{i}] \leftarrow \mathrm{p}[\mathrm{i}]\)
    \(\mathrm{R}[\mathrm{i}, \mathrm{j}] \leftarrow \mathrm{i}\)
    \(\operatorname{PS}[1] \leftarrow \mathrm{p}[1] \quad / /\) PS[i]: prefix_sum(i): Sum of all \(p[j]\) values for \(j \leq i\)
    for \(\mathrm{i} \leftarrow 2\) to n do
        \(\mathrm{PS}[\mathrm{i}] \leftarrow \mathrm{p}[\mathrm{i}]+\mathrm{PS}[\mathrm{i}-1] / /\) compute the prefix sum
    for \(\mathrm{d} \leftarrow 1\) to \(\mathrm{n}-1\) do // BSTs with \(d+1\) consecutive keys
        for \(\mathrm{i} \leftarrow 1\) to \(\mathrm{n}-\mathrm{d}\) do
        \(\mathrm{j} \leftarrow \mathrm{i}+\mathrm{d}\)
        \(c[i, j] \leftarrow \infty\)
        for \(r \leftarrow \mathrm{i}\) to j do
            \(\mathrm{q} \leftarrow \min \{\mathrm{c}[\mathrm{i}, \mathrm{r}-1]+\mathrm{c}[\mathrm{r}+1, \mathrm{j}]\}+\mathrm{PS}[\mathrm{j}]-\mathrm{PS}[\mathrm{i}-1]\}\)
            if \(\mathrm{q}<\mathrm{c}[\mathrm{i}, \mathrm{j}]\) then
                \(\mathrm{c}[\mathrm{i}, \mathrm{j}] \leftarrow \mathrm{q}\)
                \(\mathrm{R}[\mathrm{i}, \mathrm{j}] \leftarrow \mathrm{r}\)
    return \(\mathrm{c}[1, \mathrm{n}], \mathrm{R}\)
```

## Note on Prefix Sum

$\square$ We need $\mathrm{P}_{\mathrm{ij}}$ values for each $\mathrm{i}, \mathrm{j}(1 \leq \mathrm{i} \leq \mathrm{n}$ and $1 \leq \mathrm{j} \leq \mathrm{n})$,

$$
\text { where: } P_{i j}={ }_{h=i}^{j} p_{h}
$$

$\square$ If we compute the summation directly for every (i, j ) pair, the runtime would be $\Theta\left(\mathrm{n}^{3}\right)$.
$\square$ Instead, we spend $\mathrm{O}(\mathrm{n})$ time in preprocessing to compute the prefix sum array PS. Then we can compute each $\mathrm{P}_{\mathrm{ij}}$ in $\mathrm{O}(1)$ time using PS.

## Note on Prefix Sum

In preprocessing, compute for each i :
PS[i]: the sum of $p[j]$ values for $1 \leq j \leq i$
Then, we can compute $\mathrm{P}_{\mathrm{ij}}$ in $\mathrm{O}(1)$ time as follows:

$$
\mathrm{P}_{\mathrm{ij}}=\mathrm{PS}[\mathrm{i}]-\mathrm{PS}[\mathrm{j}-1]
$$

Example:

|  | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| ---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\mathrm{p}:$ | 0.05 | 0.02 | 0.06 | 0.07 | 0.20 | 0.05 | 0.08 | 0.02 |
| $\mathrm{PS}:$ | 0.05 | 0.07 | 0.13 | 0.20 | 0.40 | 0.45 | 0.53 | 0.55 |
| $\mathrm{P}_{27}=\mathrm{PS}[7]-\mathrm{PS}[1]=0.53-0.05=0.48$ |  |  |  |  |  |  |  |  |
| $\mathrm{P}_{36}=\mathrm{PS}[6]-\mathrm{PS}[2]=0.45-0.07=0.38$ |  |  |  |  |  |  |  |  |
